1. INTRODUCTION

SAILOR Compact HF SSB RE2100 is the control unit in SAILOR Compact HF SSB Programme 2000.

SAILOR Compact HF SSB Programme 2000 is a powerful, advanced, high technology short wave communication system which is extremely easy to operate.

It has been developed on the basis of S. P. Radio's many years of experience with short wave communication equipment.

It has the same high reliability as all SAILOR equipment is known for.

It is extremely easy to operate:

1. Select frequency.
2. Make your call when the tune lamp has been extinguished.

It has been constructed so that it fits in with the other units in the SAILOR Compact Programme 2000.

SAILOR HF SSB PROGRAMME 2000 CONSISTS OF THE FOLLOWING UNITS:

RE2100: Control unit with integral receiver and exciter.

T2130: 250W PEP SSB transmitter with integral power supply for RE2100. Supply voltage 24V.

AT2110: 250W PEP aerial coupler for use outdoors.

N2160: 12V DC power supply for T2130.

N2161: 110/220/240 AC, 50 Hz power supply for T2130.

1.1. GENERAL DESCRIPTION

SAILOR HF SSB RE2100 is an all solid state constructed microcomputer controlled SSB short wave telephony receiver and exciter.

SAILOR HF SSB RE2100 covers the frequency range from 100 kHz to 30 MHz in receive mode and from 1.6 MHz to 30 MHz in transmit mode.

SAILOR HF SSB RE2100 can operate in both simplex and semi-duplex.

SAILOR HF SSB RE2100 includes all ITU channels from 4 MHz to 22 MHz.

SAILOR HF SSB RE2100 includes channel scanning facilities.

SAILOR HF SSB RE2100 includes 100 quick select frequency pairs.

SAILOR HF SSB RE2100 has continuous tuning in receive mode.

SAILOR HF SSB RE2100 has clarifier function ± 150 Hz in 10 Hz steps.

SAILOR HF SSB RE2100 is fully synthesized and has a high stability reference oscillator (TCXO).

SAILOR HF SSB RE2100 has an easy to read display with red light figures.

SAILOR HF SSB RE2100 has a push-button keyboard offering an attractive tactile feeling and a safe finger-guide in the metal front. The keyboard is fitted with night-illumination of the lettering.

SAILOR HF SSB RE2100 has one key operation of the distress frequency 2182 kHz.

SAILOR HF SSB RE2100 has integral two tone alarm signal generator in accordance with SOLAS.

SAILOR HF SSB RE2100 has a special serial input (SP-BUS) enabling RE2100 to communicate with other units.

1.2. TECHNICAL DATA

(complies with SOLAS, ITU, CEPT, MPT, DOC, FTZ, KSR, FCC)

GENERAL

<u>Frequency Range:</u>	Receiver:	100 kHz to 30 MHz
	Transmitter:	1.6 MHz to 30 MHz
<u>Modes:</u>	J3E (USB/LSB), R3E and H3E (AM)	
<u>Channel Capacity:</u>	100 user defined quick-select channels and ITU defined channels in the maritime bands. Each channel contains both RX and TX frequency and mode settings.	
<u>Scanning Facilities:</u>	10 scanning programmes, each able to contain 128 pairs of frequencies.	
<u>Distress Call:</u>	Quick selection of 2182 kHz Built-in two tone alarm: 1300 Hz and 2200 Hz with a duration of 45 secs.	
<u>Operating Temperature Range:</u>	-15°C to +55°C	
<u>Frequency Stability:</u>	Better than 1.3 ppm	
<u>Primary Voltage:</u>	24V DC -10% +30%	
<u>Current Drain:</u>	Receiver (standby)	0.9A
	Transmit voice	7A
	Transmit two-tone	13A
<u>Aerials:</u>	from 7 - 15 m	

TRANSMITTER T2130

<u>Power Output:</u>	250W PEP +/-1.4 dB (T2130/I 240W PEP max.)
<u>Intermodulation:</u>	better than 32 dB below PEP
<u>Spurious Emission:</u>	better than 67 dB below PEP
<u>Harmonics:</u>	better than 43 dB below PEP or better than 67 dB below PEP with aerial coupler AT2110
<u>Carrier Suppression:</u>	better than 46 dB below PEP
<u>Audio Response:</u>	350 Hz to 2700 Hz at -6 dB

RECEIVER RE2100

<u>Receive System:</u>	Double conversion super heterodyne 1st IF 70 MHz. 2nd 10.73 MHz
<u>Selectivity:</u>	J3E (SSB) 350 Hz to 2700 Hz at -6 dB H3E (AM) +3.3 kHz at -6 dB

1.2. TECHNICAL DATA cont.:

<u>Sensitivity:</u>	J3E (SSB) <10 dB/uV for 20 dB SINAD H3E (AM) <24 dB/uV for 20 dB SINAD
<u>Spurious and IF Rejection:</u>	better than -70 dB
<u>Cross Modulation:</u>	better than 90 dB/uV (CEPT method of test)
<u>Desensitization:</u>	better than 100 dB/uV (CEPT method of test)
<u>AGC:</u>	less than 2 dB audio level change from 10 dB/uV to 80 dB/uV. Fast attack, slow release time.
<u>Intermodulation:</u>	better than 90 dB/uV (CEPT method of test)
<u>Spurious Emission:</u>	better than 1 nW into dummy aerial
<u>Clarifier:</u>	<u>±</u> 150 Hz in steps of 10 Hz
<u>Squelch:</u>	Voice activated, opens for SINAD >6 dB
<u>Audio Power:</u>	5 Watt, 8 ohm, less than 10% distortion 10 Watt, 4 ohm, less than 10% distortion

AERIAL COUPLER AT2110

<u>Power:</u>	250W PEP
<u>Aerial:</u>	7 - 15 m
<u>Temperature Range:</u>	-25°C to +70°C
<u>Tuning Time:</u>	Typically less than 2 secs (learn mode typ. 30 secs)

ACCESSORIES

<u>Loudspeaker:</u>	H2054 see special brochure H2074 see special brochure
<u>Power Supplies:</u>	N2160, 12V DC -10% +30% to 24V DC max. output current 18 Amps. N2161, 110V, 115V, 220V, 245V AC, 50-60 Hz to 29V DC max. output current 20 Amps. Automatic change-over.
<u>Weight:</u>	RE2100: 4.5 kg T2130: 14 kg AT2110: 4.5 kg

Dimensions:

1.3. CONTROLS

Volume control and on/off switch for the mains.

Manual RF gain control.

Tunes the receive frequency down.

Tunes the receive frequency up.

Switches between clarifier (10 Hz steps) and tune of receive frequency.

Selects receive functions or converts a channel number to the corresponding frequency.

Selects channel functions.

Selects transmit functions or converts a channel number to the corresponding frequency.

Selects the built-in dummy load in the aerial coupler.

Transmits the distress signal when pressed together with TEST ALARM.

Selects the distress frequency 2182 kHz.

Acoustic check of the alarm signal generator.

DIM

Reduces/increases the display light or switches on/off the display and keyboard panel.

SQ

Switches the squelch function on/off.

MODE

Selects modulation type J3E, R3E, H3E and J3E lower side band.

SC

Selects the scan programme.

SC

ADD

Adds a new channel to the scanning table.

SC

DEL

Deletes a channel from the scanning table.

7

Digits from 1 to 0.

ENT

Terminates the keying-in sequence, stops the alarm signal, stops the scanning, and stops the TX tuning.

.

Sets the decimal point for the frequency in kHz.

CH

(Digits 0-99)

ADD

Adds the RX/TX frequency to the channel number.

CH

(Digits 0-99)

DEL

Deletes the RX/TX frequency from the channel

1.4. PRINCIPLE OF OPERATION

SAILOR Compact HF SSB RE2100 is the control unit in SAILOR Compact HF SSB Programme 2000. It contains following circuits.

PROCESSOR UNIT

This unit controls all modules and operate as interface between the user and the radio (keyboard, display). Nearly all communication from the microprocessor to the modules is done on an internal serial bus (SPI).

The unit holds all memory, and all user defined memory is in an EEPROM, so even when supply voltage is removed, the contents of the memory is preserved. If the supply voltage to the RE2100 gets too low, the display will show error 20, and the performance of the RE2100 will be reduced.

There is also an external serial bus (SP-Bus). This bus is used to communicate with other units in the SAILOR Compact HF SSB Programme 2000, e.g. the transmitter T2130.

The microprocessor also generates the alarm tones (1300 Hz, 2100 Hz).

DISPLAY UNIT

This unit contains the display and the field strength meter.

SYNTHESIZER UNIT

This unit contains all frequency generating parts.

There is only one reference oscillator which is a temperature compensated crystal oscillator (TCXO) with a frequency of 10.73 MHz.

Both receiver and exciter are using two LO-signals. These signals are generated in two separate PLL's, one having output frequencies from 70 MHz to 100 MHz and the other having output frequencies of 59.27 MHz and 80.73 MHz. The synthesizer which covers from 70 to 100 MHz is a fractional synthesizer with a resolution of 10 Hz.

The other synthesizer is a conventional synthesizer. It has two output frequencies, one for lower sideband 80.73 MHz and another for upper sideband 59.27 MHz.

RECEIVER FRONT END

This unit contains input protection circuit, input filters, mixer and 70 MHz IF.

The input filter is a mixture of lowpass, highpass and bandpass filter to obtain max. performance in the entire band from 100 kHz to 30 MHz.

The mixer is a FET mixer with a high level LO-injection to give the mixer good high signal quality. The mixer is followed by a 70 MHz bilitic quartz filter with a bandwidth of 15 kHz.

RECEIVER UNIT

This unit contains all necessary circuits to convert a 70 MHz IF signal to an audio signal.

It starts with the second mixer which is a FET mixer. From the mixer the signal is fed to a high order monolithic quartz filter, one for AM and one for SSB. The type of filter is selected from the microprocessor.

1.4. PRINCIPLE OF OPERATION cont.:

From the filter the signal is fed to the 10.73 MHz IF amplifier. The gain of this amplifier is regulated from the AGC amplifier. The regulated IF amplifier is followed by a ceramic filter to reduce the wideband noise. The signal is from here fed to the demodulator, which can operate as an SSB detector or an AM detector controlled from the microprocessor. The detector is followed by a filter circuit. In AM mode the filter width is from 70 Hz to 3000 Hz, and in SSB mode the filter is from 300 Hz to 3000 Hz. From here the AF signal passes some switches and then it is amplified in three AF amplifiers, one for the microtelephone earpiece, one for the 0 dBm output, and an amplifier with volume control for the AF signal to the AF power amplifier in T2130.

The signal from the AF filters is also fed to the voice controlled squelch. This contains a limiting amplifier, a frequency to voltage converter, and a threshold amplifier. On/off switching of the squelch is controlled by the microprocessor.

In scan mode the squelch is used to detect if there is signal on the channel in question.

EXCITER UNIT

This unit contains all necessary circuits to generate an SSB/AM signal in the frequency range from 1.6 - 30 MHz.

It starts with a compressor and AF amplifier.

The AF signal is fed to the balanced modulator to produce a double sideband signal on 10.73 MHz.

The DSB signal is fed to the LSB filter where only the lower sideband passes through. The LSB signal is fed to a step attenuator, which is controlled from the microprocessor. From the step attenuator the signal is fed to the first mixer, and the frequency is converted to 70 MHz. If 59.27 MHz LO-signal is used, the signal will be lower sideband. If 80.73 MHz LO-signal is used, the signal will be upper sideband. From the mixer the signal is fed to an amplifier, 70 MHz crystal filter and an amplifier. From the amplifier the signal is fed to the second mixer which converts the frequency from 1.6 MHz to 30 MHz.

After the mixer a lower side signal is converted to an upper sideband signal, and an upper sideband signal is converted to a lower sideband signal. The output of the mixer is fed to the power unit.

POWER UNIT

This unit contains the final amplifying and filtering of the RF signal, and produces all necessary supply voltages for the modules in RE2100.

The signal from exciter unit is first amplified, then filtered in a 30 MHz lowpass filter and then amplified to a level of approx. 2 mW.

The input voltages from T2130 is +18V and 9V. These voltages passes through seven series regulators to produce the necessary supply voltages to RE2100. A special +15V for the exciter is controlled from the microprocessor, so when the transmitter has not been used for two minutes, it is switched off to reduce the power consumption in standby.

3. SERVICE

3.1. MAINTENANCE

PREVENTIVE MAINTENANCE

If the HF SSB RE2100 has been installed in a proper way the maintenance can, dependent on the environments and working hours, be reduced to a performance check at the service workshop at intervals, not exceeding 12 months. A complete performance check list is enclosed in this manual, chapter 3.5 PERFORMANCE CHECK.

Inspection of the antenna, cables, and plugs for mechanical defects, salt deposits, corrosion, and any foreign bodies shall be done at regular intervals not exceeding 12 months.

Along with each RE2100 a test sheet is delivered in which all the measurements, made in the test department of the factory, are listed. If the control measurings made in the service workshop should not show the same values as those listed in the test sheet, the set must be adjusted as specified in chapter 3.7. ADJUSTMENT PROCEDURE.

3.2. ALIGNMENT INSTRUCTIONS

INTRODUCTION

The measuring values indicated in chapter 5. CIRCUIT DESCRIPTION AND SCHEMATIC DIAGRAMS are typical values and as indicated it will be necessary to use instruments in absolute conformity with the below list:

3.3. PROPOSAL FOR NECESSARY TEST EQUIPMENT

OSCILLOSCOPE:

Bandwidth	DC-35 MHz
Sensitivity	2mV/div
Output Impedance	1 Mohm//20 pF
E.g. Philips type	PM3050

PASSIVE PROBE:

Attenuator	20 dB
Input Impedance	10 Mohm//15 pF
Compensation Range	10-30 pF
E.g. Philips type	PM8936/091

MULTIMETER:

Sensitivity DC (f.s.d.)	100 mV
Input Impedance	10 Mohm
Accuracy DC (f.s.d.)	1.5%
E.g. Philips type	PM2505

FREQUENCY COUNTER:

Frequency Range	100 Hz - 120 MHz
Resolution	1 Hz at $f = 100$ MHz
Accuracy	$1 \cdot 10^{-7}$
Sensitivity	100 mV RMS
Input Impedance	1 Mohm/30 pF
E.g. Philips type	PM6669/031

HF SIGNAL GENERATOR:

Frequency Range	100 kHz - 100 MHz
Output Voltage:	0dB/uV - 120 dB/uV
Output Impedance	50 ohm
Type of Modulation	AM
Modulation Frequency	External
E.g. Marconi type	2019

LF SIGNAL GENERATOR:

Frequency Range	10 Hz - 10 kHz
Output Voltage	20 mV _{RMS} - 1V _{RMS}
Output Impedance	600 ohm
Output Waveform	sine wave
E.g. Philips type	PM5110

LF DISTORTION METER:

Frequency Range	$f = 1000$ Hz
Distortion Range (f.s.d.)	1-10%
Input Impedance	1 Mohm
Accuracy (f.s.d.)	3%
E.g. Philips type	PM6309

3.3. PROPOSAL FOR NECESSARY TEST EQUIPMENT cont.:

DIODE PROBE

LAYOUT OF THE PROBE

50 OHM DUMMY LOAD

50 ohm → 50 ohm:

EMF-loss 20 dB

3.3. PROPOSAL FOR NECESSARY TEST EQUIPMENT cont.:

POWER SUPPLY:

V_{out1}	18V DC
V_{out2}	18V DC
I_{out1}	2 Amp DC
I_{out2}	0.5 Amp DC
E.g. 2 pcs. ELCANIC type	3010

TESTBOX

To test all the functions of the RE2100 is very difficult when no transmitter T2130 is available. For that reason S. P. Radio has developed and produced a testbox. When using this testbox it is possible in an easy way to test all the inputs and outputs of the RE2100.

The testbox has a built-in AF amplifier, which makes it possible to connect a loudspeaker directly to the testbox.

The testbox has a built-in unit to control the function of the SP-BUS output. By means of the built-in light emitting diodes and switches it is possible to control all the functions of the RE2100.

Specification of measuring instruments, which can be connected to the testbox is given in the beginning of this chapter, and to this list an 8 ohm loudspeaker can be added.

The below diagram shows the electric wiring inside the testbox:

COMPONENT LOCATION TESTBOX

3.3. PROPOSAL FOR NECESSARY TEST EQUIPMENT cont.:

The below diagram shows how to connect the testbox with the RE2100 and the external instruments.

If no testbox is available, it is possible to operate the RE2100 by connecting the power supply directly to the 25-pin connector, which is located at the back of the RE2100. In this 25 pin connector it is possible to find all the other inputs, outputs, and testpoints. The pin configuration for this connector is listed in chapter 2.3. ELECTRICAL CONNECTION AND ASSEMBLING. But it is only necessary to establish the following connections:

pin No. 10 -18V/0.2 Amp.
pin No. 11 + 9V/0.5 Amp.
pin No. 12 +18V/0.8 Amp.
pin No. 5 GND

The handset is connected directly to the 9-pin connector at the back of the RE2100.

3.4. TROUBLE SHOOTING

Trouble shooting should only be performed by persons with sufficient technical knowledge, who have the necessary measuring instruments at their disposal, and who have carefully studied the operation principles and structure of the SAILOR Compact HF SSB System.

SAILOR HF SSB RE2100 has a number of trimming cores and trimmers, which must not be touched, unless adjustments as specified in chapter 3.7. ADJUSTMENT PROCEDURE, can be made.

When measuring the units, short-circuits must be avoided as the transistors would then be spoiled.

LOCATING THE FAULTY UNIT

When a fault has been observed in the HF SSB system, it can be difficult to find out in which unit the fault can be located.

The first thing to check, is whether the fault is somewhere in the aerial circuit, the handset or in the power source.

If the fault is not found there, check if an error message has been shown in the RX display of the RE2100.

The error codes listed below are error messages, which are generated by the RE2100, and they therefore indicate a fault in this unit.

ERROR CODES

- | | |
|----|--|
| 00 | Internal power supply is low.
Check the power connections to the RE2100, or check the internal power regulators. |
| 11 | Illegal transmitting frequency.
The TX frequency, of which a tone sequence has been tried, is not legal. |
| 12 | Illegal transmitting mode.
The TX emission mode is not legal for transmitting. |
| 15 | Key sequence is not finished by the <ENT> key. |
| 20 | The communication link to the transmitter T2130 is interrupted.
Check the coax cable to the T2130 from RE2100. |
| 21 | The communication link between RE2100 and control unit C2140 or DSC/telex RM2150/RM2151 has been stopped. Check the SP-BUS coax cable to the external equipment. If the "Error 21" flashes up again after the button <STOP/ENT> has been pressed, then check the SP-BUS interrupt line (J03-5 pin 6). This line has to be normal "High" (approx. +5V). |

The error codes listed below are error messages, which are generated by the HF transmitter T2130, and they therefore indicate a possible fault in this unit.

3.4. TROUBLE SHOOTING cont.:

These error codes are described more detailed in the instruction manual for T2130, chapter 2.3. SYSTEM DESCRIPTION AND TROUBLE SHOOTING, and in the chapter 3.4. TROUBLE SHOOTING.

ERROR CODES

- 70 Motor circuit error AT2110.
See instruction manual for T2130, chapter 3.4.
- 71 Internal signal error.
See instruction manual for T2130, chapter 3.4.
- 72 Internal signal error.
See instruction manual for T2130, chapter 3.4.
- 73 High standing wave ratio (SWR) in the tuning of the AT2110.
Check the aerial and see instruction manual for T2130, chapter 3.4.
- 74 Transmitter temperature too high.
Let the transmitter T2130 have a pause and see instruction manual for T2130, chapter 3.4.
- 75 High standing wave ratio (SWR) when transmitting.
Check the aerial and see instruction manual for T2130, chapter 3.4.
- 76 Battery voltage low.
Check the condition of the batteries and the power cables. See instruction manual for T2130, chapter 3.4.
- 77 Temperature sensor error.
See instruction manual for T2130, chapter 3.4.
- 78 Internal high standing wave ratio (SWR).
See instruction manual for T2130, chapter 3.4.

If the error codes indicate that the fault may be found in the RE2100, the fault is probably no transmitter signal from the RE2100. The exciter can then, without any damage to the transmitter, be set on by activating the test programme SP-05-0.

The error codes do not indicate any receiver fault.

A receiver fault can be in the aerial coupler AT2110, in the transmitter T2130, or in the receiver unit.

To separate a fault in these units, disconnect the aerial cable at the back of RE2100 and connect a wire to the RE2100 coax socket. Try to find a broadcast station and check the receiver. If the fault is still present, it must be located in the RE2100 unit.

3.4. TROUBLE SHOOTING cont.:

LOCATING THE FAULTY MODULE

If the fault has been located to the RE2100, the exciter can be activated in test programme SP-05-0. The receiver is always activated, when no test programme is activated.

Check the connections to the modules in the RE2100.

The power supply should be the first thing to control, the voltage is indicated in the diagram of each module.

If the power supply is present, control the amplitude of the local oscillator signals.

The next thing to control is whether the other inputs to the module are present. They are indicated in the diagrams of each module with reference to a special set-up of the RE2100.

It should now be possible to locate the faulty module.

LOCATING THE FAULTY CIRCUIT

When the faulty module has been found, it can be difficult to find the faulty circuit or component.

One way is to change the module. If this is not possible, the faulty component or circuit can be found in a more systematic way by using the chapter 3.6.

MODULE PERFORMANCE CHECK.

Chapter 3.6. MODULE PERFORMANCE CHECK is divided into sections with a headline indicating a possibility of checking some main parameters, and this may be a great help.

3.5. PERFORMANCE CHECK

GENERAL

A performance check is intended to be used as a check after repair and before reinstallation of the equipment.

A performance check can be used to check the equipment after a certain time to make sure that the equipment is according to the required technical specifications.

The performance check is divided into three sections, and it is possible to perform one of the sections or all of them.

Connect the RE2100 with the textbox for the RE2100 and connect the power supply and the handset to the textbox as described in chapter 3.3. PROPOSAL FOR NECESSARY TEST EQUIPMENT.

If no textbox is available, it is possible to operate the RE2100 by connecting the power supply directly to the 25 pin connector, which is located at the back of the RE2100. The pin configuration for this connector is listed in chapter 2.3. ELECTRICAL CONNECTION AND ASSEMBLING. But it is only necessary to establish the following connections:

pin No. 10	-18V/0.2 Amp.
pin No. 11	+ 9V/0.5 Amp.
pin No. 12	+18V/0.8 Amp.
pin No. 5	GND

The handset is connected directly to the 9 pin connector at the back of the RE2100.

This chapter includes a number of measurements where a signal generator is needed. The output level of the generator is, in this manual, expressed in terms of the Electromotive Force (EMF), and it is measured in terms of the unit: dB/uV = 20 log(EMF/1uV), (dB above one microvolt).

The output level from signal generators in general is sometimes expressed in terms of the available power P_a , which is measured in terms of the unit: dBm = 10 log(P_a /1mW), (dB above one milliwatt). For this reason the conversion formulas between EMF and available power and vice versa are given here:

$$P_a \text{ (dBm)} = \text{EMF (dB/uV)} - 113 \text{ dB}$$

$$\text{EMF (dB/uV)} = P_a \text{ (dBm)} + 113 \text{ dB}$$

where P_a is the available power and EMF is the Electromotive Force of the generator.

3.5.1. PERFORMANCE CHECK OF DISPLAY AND KEYBOARD

Connect the RE2100 with the testbox for RE2100. Connect the power supply +18V/2A, the loudspeaker, and a coax cable from the RE2100 SP-BUS output socket to the proper input terminals on the testbox.

The necessary test equipment to carry out a performance check is described in this manual chapter 3.3. PROPOSAL FOR NECESSARY TEST EQUIPMENT.

3.5.1.1. Performance Check of Display

1. Select test programme SP-00-2.
2. Control that the display is switched between all possible combinations of lighted bars.
3. Control that the mode indicating bars are toggled.
4. Control that the power reduction bars are alight.
5. Press the keyboard ENT key.
6. Select test programme SP-00-3.
7. Control that the two led's marked SP-BUS-TEST on the testbox are alight.
8. Press the keyboard TUNE button.
9. Turn the RF GAIN button fully counter clockwise.
10. Control that the bars in the signal meter are all alight.
11. Turn the RF gain fully clockwise.

3.5.1.2. Performance Check of Keyboard

1. Turn the VOL-OFF button fully counter clockwise and then fully clockwise.
2. Control that the testbox led marked SUPPLY ON/OFF can be switched on and off by the VOL-OFF button.
3. Press the keyboard buttons to key-in the receiver frequency 12345.6 kHz.
4. Press the keyboard button ENT.
5. Control that noise is heard from the loudspeaker.
6. Press the handset button TX.
7. Control that the point in the TX frequency window is toggled.

3.5.1. PERFORMANCE CHECK OF DISPLAY AND KEYBOARD cont.:

8. Press the keyboard buttons while the point is toggled to key-in the transmitter frequency 7890.0 kHz.
9. Press the keyboard button ENT.
10. Press the keyboard button CH.
11. The display will now show 'CH-----'.
12. Press the keyboard button SC.
13. The display will now show 'SC X'.
14. Press the keyboard button RX.
15. The display will now show '12345.6 kHz'
'7890.0 kHz'.
16. Control that the emission mode can be toggled by pressing the keyboard button MODE.
17. Control that the display light can be dimmed by pressing the keyboard button DIM.
18. Control that the led marked AGC can be toggled by pressing the keyboard button AGC.
19. Control that the led marked SQ can be toggled by pressing the keyboard button SQ.
20. Press the keyboard TUNE/CLARIF button.
21. Control that the RX frequency displayed changes to show the 10 Hz decimal '12345.60 kHz'.
22. Press the keyboard FREQ error buttons to toggle the 10 Hz decimal up and down.
23. Press the keyboard TUNE/CLARIF button.
24. Press the keyboard FREQ error buttons to toggle the 100 Hz decimal up and down.
25. Press the keyboard 2182 button.
26. Control that the display shows '2182.0 kHz'
'2182.0 kHz'
27. Press the keyboard TEST ALARM button.
28. Control that the alarm tones can be heard in the handset earpiece.
29. Press the keyboard button ENT.
30. Press the keyboard buttons SEND ALARM and TEST ALARM.
31. Control that the display shows 'Error 20'
'2182.0 kHz'
when these two buttons are pressed simultaneously.

3.5.2. PERFORMANCE CHECK OF RECEIVER

Connect the RE2100 with the textbox for RE2100 and connect the power supply and a loudspeaker to the proper inputs on the textbox.
The necessary test equipment to carry out a performance check is described in this manual, chapter 3.3. PROPOSAL FOR NECESSARY TEST EQUIPMENT.

This chapter contains the following sections:

- 3.5.2.1. Performance Check of Receiver Sensitivity
- 3.5.2.2. Performance Check of Receiver Distortion
- 3.5.2.3. Performance Check of Receiver Audio Passband
- 3.5.2.4. Performance Check of Receiver Clarifier and Frequency
- 3.5.2.5. Performance Check of Receiver AGC
- 3.5.2.6. Performance Check of Receiver Squelch
- 3.5.2.7. Performance Check of Receiver External Connections

3.5.2.1. Performance Check of Receiver Sensitivity

1. Connect the signal generator to the aerial socket through the 50 ohm dummy load described in this manual, chapter 3.3.
2. Connect a voltmeter or a distortion meter to the 0 dBm output on the textbox.
3. Choose receiver frequency f_{RX} , generator frequency f_G , and generator output level V_G according to table in point 5.
4. Measure the signal to noise ratio SND/N with the distortion meter or the voltmeter as described in point 6. The measured signal to noise ratio shall be better than 20 dB.

Signal Generator			RE2100		
f_G (MHz)	V_G (EMF)	MODE	f_{RX} (MHz)	MODE	
0.100	30 dB/uV	AM 30% with 1kHz	0.100	H3E	
0.384			0.384		
0.385			0.385		
1.599			1.599		
1.601	11 dB/uV	CW	1.600	J3E	
2.101			2.100		
2.182	25 dB/uV	AM 30% with 1 kHz	2.182	H3E	FIXED
4.500	11 dB/uV	CW	4.499	J3E	
4.501			4.500		
9.000			8.999		
9.001			9.000		
13.251			13.250		
18.000			17.999		
18.101			18.100		
25.001			25.000		
29.998	11 dB/uV	CW	29.999	J3E/LSB	

3.5.2. PERFORMANCE CHECK OF RECEIVER cont.:

6. Measurement of the signal to noise S_{ND}/N.
With the specified test signal applied to the receiver, the measurement of S_{ND}/N is performed as described below.

SSB MODE

- Turn the RF-GAIN control fully clockwise and make sure that the AGC is operative.
- Notice the output LF level by means of a voltmeter.
- Turn the AGC OFF and adjust the RF-GAIN control to achieve the output level found in point 6.b.
- Change the signal generator frequency f_G to $f_{RX} + 30$ kHz and notice the reduction of the LF output level, which expresses the signal to noise ratio.

AM MODE

- Turn the RF-GAIN fully clockwise and make sure that the AGC is operative.
- Notice the output level by means of a voltmeter.
- Remove modulation from the generator signal and notice the reduction of the output, which expresses the signal to noise ratio.

3.5.2.2. Performance Check of Receiver Distortion

To carry out the check as described below, it is necessary to have a distortion meter at your disposal. If this is not possible, the check can be done by an oscilloscope, but please note that it should not be possible to see a distortion of 10% or less on the oscilloscope.

- Connect a distortion meter to the 0 dBm output on the testbox.
- Connect a signal generator to the aerial socket through a 50 ohm dummy load.
- Choose receiver frequency f_{RX} generator frequency f_G and generator output level V_G according to point 5.
- Measure the signal distortion S_{ND}/N_D with the distortion meter. The measured distortion S_{ND}/N_D shall be better than the figures given in the table in point 5.

5.

Signal Generator			RE2100		
f_G (kHz)	V_G (EMF)	MODE	f_{RX} (kHz)	MODE	Distortion S _{ND} /N _D
2182	83 dB/uV	AM 30% with 1 kHz	2182	H3E	2.0%
2183	83 dB/uV	CW	2182	J3E	1.5%

3.5.2. PERFORMANCE CHECK OF RECEIVER cont.:

3.5.2.3. Performance Check of Receiver Audio Passband

1. Connect the signal generator to the aerial socket through a 50 ohm dummy load.
2. Connect a voltmeter to the 0 dBm output on the testbox.
3. Choose receiver frequency f_{RX} , generator frequency f_G , generator output level V_G according to point 7.
4. **USB-SSB MODE**
 - a. Set the f_{RX} , f_G and V_G according to point 1 in the table in point 7.
 - b. Turn the RF-GAIN control fully clockwise and make sure that the AGC is operative.
 - c. Notice the AF output level by means of the voltmeter.
 - d. Turn the AGC off and adjust the RF-GAIN control to achieve the output level found in point 4.c.
 - e. Change the signal generator frequency f_G , and the generator output level V_G according to point 2 in table 7, and control the voltage on 0 dBm output to be above the value found in point 4.c.
 - f. Change f_G according to point 3 in table 7 and control the voltage on 0 dBm output to be below the value found in point 4.c.
5. **LSB-SSB MODE**

Carry out point 4. USB-SSB MODE, but use the figures mentioned in point 7, under "lower sideband audio passband".
6. **AM MODE**
 - a. Set f_{RX} , f_G and V_G according to point 4 in table 7.
 - b. Notice the AF output level by means of the voltmeter.
 - c. Change the modulation frequency according to the figures in point 5 in table 7, and control that the voltage on 0 dBm output has not dropped 6 dB below the value found in point 6.b.
 - d. Change the modulation frequency according to the figures in point 6 in table 7, and control that the voltage on 0 dBm output has dropped more than 20 dB below the value found in point 6.b.

3.5.2. PERFORMANCE CHECK OF RECEIVER cont.:

7.

Signal Generator			RE2100		
f _G (kHz)	V _G (EMF)	MODE	f _{RX} (kHz)	MODE	Point
Upper sideband audio passband					
4126	53 dB/uV	CW	4125	J3E	1
4125.35	59 dB/uV				2
4127.7					
4128.1	73dB/uV				3
Lower sideband audio passband					
4124	53dB/uV	CW	4125	LSB/J3E	1
4124.65	59dB/uV				2
4122.3					
4121.9	73dB/uV				3
Audio passband by amplitude modulation					
4125	63dB/uV	AM 30% with 1 kHz	4125	H3E	4
		AM 30% with 100 Hz			5
		AM 30% with 3000 Hz			
		AM 30% with 6000 Hz			6

3.5.2.4. Performance Check of Receiver Clarifier and Frequency

1. Connect the signal generator to the aerial socket through a 50 ohm dummy load.
2. Choose receiver frequency f_{RX} , signal generator frequency f_G , and the generator output level V_G according to point 6.
3. Connect a frequency counter to 0 dBm output on the testbox.
4. Activate the frequency tune and let the frequency f_{RX} change in 100 Hz steps and control with the counter that this happens.
5. Activate the clarifier tune and let the frequency f_{RX} change in 10 Hz steps and control with the counter that this happens.

3.5.2. PERFORMANCE CHECK OF RECEIVER cont.:

6.

Signal Generator			RE2100	
f_G (kHz)	V_G (EMF)	MODE	f_{RX} (kHz)	MODE
25001.0	73dB/uV	CW	25000.1	J3E

7. With the frequency and clarifier tune, set the frequency f_{RX} to 25000.07 kHz.

8. Control with the counter the output frequency to be 930 Hz ± 10 Hz.

NOTE! The frequency tolerance of the signal generator shall be better than ± 2.5 Hz 0.1 ppm. If not and if the counter has a frequency tolerance of 0.1 ppm, carry out the measurement in section 3.5.3.2. Performance Check of Exciter Frequency.

3.5.2.5. Performance Check of Receiver AGC

1. Connect the signal generator to the aerial socket through a 50 ohm dummy load.
2. Connect a voltmeter to the 0 dBm output on the testbox.
3. Choose receiver frequency f_{RX} , generator frequency f_G , and generator output level V_G according to the table in point 4.

4.

Signal Generator			RE2100	
f_G (kHz)	V_G (EMF)	MODE	f_{RX} (kHz)	MODE
1991	8dB/uV	CW	1990	J3E

5. Turn the RF-GAIN control fully clockwise, and make sure that the AGC is operative.
6. Notice the AF output level by means of the voltmeter at the 0 dBm output.
7. Increase the output level of the signal generator to 28 dB/uV.
8. The increase in AF output level measured with the voltmeter shall be less than 3 dB.
9. Notice the AF output level by means of the voltmeter at the 0 dBm output.
10. Turn the AGC OFF and adjust the RF-GAIN control to achieve the output level found in point 9.
11. Disconnect the signal generator from the aerial socket and notice the reduction of the AF output level, which shall be at least 35 dB.
12. Reconnect the signal generator to the aerial socket.

3.5.2. PERFORMANCE CHECK OF RECEIVER cont.:

13. Turn the RF-GAIN control fully clockwise and make sure that the AGC is operative.
14. Notice the AF output level by means of the voltmeter at the 0 dBm output.
15. Increase the output level of the signal generator to 78 dB/uV.
16. The increase in AF output level measured with the voltmeter shall be less than 2 dB.
17. Connect 0 dBm output from the testbox to channel A on the oscilloscope.
18. Connect the SP-BUS output socket on RE2100 to channel B on the oscilloscope.
19. Select test programme SP-04-6.
20. Set the timebase on the oscilloscope to 20 msec/div.
21. Set the oscilloscope to trig on channel B.
22. Control that the oscilloscope displays the response shown in figure SSB attack.

SSB ATTACK

A = 0.5V/div
B = 5V /div.

20 msec/div

23. Set the timebase on the oscilloscope to 200 msec/div.
24. Control that the oscilloscope displays the response shown in figure SSB decay.

3.5.2. PERFORMANCE CHECK OF RECEIVER cont.:

SSB DECAY

A = 0.5V/div.
B = 5V /div.

200 msec/div.

25. Select test programme SP-04-7.
26. Set the timebase on the oscilloscope to 50 msec/div.
27. Set the signal generator in amplitude modulation mode, modulating LF signal 1.0 kHz and modulating index $M = 0.3$.
28. Control that the oscilloscope displays the response shown in figure AM attack and decay.

AM ATTACK AND DECAY

A = 1.0V/div.
B = 5.0V/div.

50 msec/div.

3.5.2. PERFORMANCE CHECK OF RECEIVER cont.:

3.5.2.6. Performance Check of Receiver Squelch

1. Connect a signal generator to the aerial socket through a 50 ohm dummy load.
2. Choose the receiver frequency f_{RX} , signal generator frequency f_G , and the generator output level V_G according to table in point 8.
3. Make sure that the AGC and SQUELCH are active and adjust the AF volumen until a tone is heard in the loudspeaker.
4. Disconnect the signal generator from the aerial socket on the RE2100. You will now hear the receiver noise from the loudspeaker.
5. Control that the AF output is muted after about 10 secs.
6. Connect the signal generator to the aerial socket again.
7. Control that the squelch opens instantly and that you now hear a 1 kHz tone from the loudspeaker.
8. Control that the squelch closes after about 10 secs.

9.

Signal Generator			RE2100	
f_G (kHz)	V_G (EMF)	MODE	f_{RX} (kHz)	MODE
1991	13dB/uV	CW	1990	J3E

3.5.2.7. Performance Check of Receiver External Connections

1. If no testbox for RE2100 is available, the connections can be found and checked in the 25 pin connector and the 9 pin connector at the back of the RE2100.
2. Press the front panel key <2182> fixed.
3. Control that the light emitting diodes names distress and +18 handset at the testbox are alight.
4. Connect a signal generator to the aerial socket through a 50 ohm dummy load.
5. Choose receiver frequency f_{RX} , signal generator frequency f_G and the generator output V_G according to table in point 6.

6.

Signal Generator			RE2100	
f_G (kHz)	V_G (EMF)	MODE	f_{RX} (kHz)	MODE
2183	50dB/uV	CW	2182	J3E

7. A 1 kHz tone shall be heard from the loudspeaker and approx. seven bars in the signal strength meter are alight.

3.5.2. PERFORMANCE CHECK OF RECEIVER cont.:

8. Activate the RX mute switch on the testbox.
9. No tone or noise shall now be heard from the loudspeaker and approx. 2 bars in the signal strength meter are alight.
10. Release the RX mute switch.
11. Activate the TEST ALARM button on RE2100 and control that the alarm tones can be heard in the handset earpiece.

3.5.3. PERFORMANCE CHECK OF EXCITER

Connect the RE2100 with the testbox for RE2100.

Connect a $\pm 18\text{V}/2\text{A}$ power supply, an LF signal generator, and the handset to the proper inputs on the testbox.

The necessary test equipment for executing the performance check is described in this manual, chapter 3.3. PROPOSAL FOR NECESSARY TEST EQUIPMENT.

This chapter consists of the following sections:

- 3.5.3.1. Performance Check of Exciter Output Signal
- 3.5.3.2. Performance Check of Exciter Frequencies and Classes of Emission
- 3.5.3.3. Performance Check of Exciter Microphone Amplifier and LF Response
- 3.5.3.4. Performance Check of Exciter Step Attenuator

3.5.3.1. Performance Check of Exciter Output Signal

1. Connect a 50 ohm resistor to the aerial socket. Two 100 ohm resistors in parallel soldered on a coax cable connected to the aerial socket are sufficient.
2. Connect an oscilloscope through a 10:1 probe to the 50 ohm resistor.
3. Connect the LF signal generator to the AF TO TX input on the testbox.
4. Select test programme SP-05-1 ($f_{TX} = 22.000 \text{ kHz}$).
5. Set the testbox switch RF ON/OFF on.
6. Adjust the LF signal generator to an output of 1Vpp ($0.350\text{V}_{\text{RMS}}$) and a frequency of 1600 Hz.
7. Control that the HF output shown on the oscilloscope is $3.50 \pm 0.50\text{Vpp}$.
8. Readjust the oscilloscope gain until full deflection (8 div.) is seen on the screen.
9. Select test programme SP-05-5 ($f_{TX} = 14.900 \text{ kHz}$).
10. Control that deflection now seen is approx. $8.0 \pm 1.0 \text{ div.}$
11. Select test programme SP-05-4 ($f_{TX} = 28.000 \text{ kHz}$).
12. Control that deflection now seen is approx. $8.0 \pm 1.0 \text{ div.}$
13. Select test programme SP-05-6 ($f_{TX} = 1.600 \text{ kHz}$).
14. Control that deflection now seen is approx. $8.0 \pm 1.0 \text{ div.}$
15. Set the testbox switch RX ON/OFF off.
16. Select test programme SP-05-0 ($f_{TX} = 22.000 \text{ kHz}$).

3.5.3. PERFORMANCE CHECK OF EXCITER cont.:

17. Set the testbox switch MIC.KEY on.
18. Control that the HF output shown on the oscilloscope is $4.0 \pm 0.5V_{pp}$ and that it is a two tone signal which is displayed.
19. Control that approx. 7 bars in the signal strength meter are alight.
20. Set the testbox switch MIC.KEY off.
21. Activate the handset key and control that the two tone signal is displayed on the oscilloscope screen.
22. Activate the keyboard button TUNE.
23. Activate the keyboard button TEST ALARM.
24. Control that the alarm tone can be heard in the handset earpiece.

3.5.3.2. Performance Check of Exciter Frequencies and Classes of Emission

1. If only this section is performed, please start by carrying out the section 3.5.3.1. point 1, 2, and 3.
2. Select test programme SP-05-6 ($f_{TX} = 1.600 \text{ kHz}$).
3. Set the testbox switch RF ON/OFF on.
4. Adjust the LF signal generator to an output of $1V_{pp}$ ($0.35V_{RMS}$) and a frequency of 1600 Hz.
5. Adjust the oscilloscope gain until full deflection (8 div.) is seen on the screen.
6. Toggle the MODE switch on RE2100 between J3E, R3E, H3E, and TELEX, and control that the deflection is approx. the same in all the classes of emission $8.0 \pm 1.0 \text{ div.}$
7. Disconnect the LF signal generator.
8. Select the emission mode H3E on RE2100 and control that the deflection seen on the oscilloscope is $4.6 \pm 0.5 \text{ div.}$
9. Select the emission mode R3E on RE2100 and control that the deflection seen on the oscilloscope is $1.2 \pm 0.2 \text{ div.}$
10. Select test programme SP-05-4 ($f_{TX} = 28.000 \text{ MHz}$).
11. Select the emission mode H3E on RE2100.
12. Connect a frequency counter through a 10:1 probe to the 50 ohm resistor at the HF output socket.
13. Control that the frequency is $28,000,000 \pm 10 \text{ Hz}$.
NOTE! The frequency tolerance of the counter shall be better than 0.1 ppm.
14. Set the testbox switch RF 50% DUTY CYCLE on.

3.5.3. PERFORMANCE CHECK OF EXCITER cont.:

15. Connect the oscilloscope through a 10:1 probe to the 50 ohm resistor at the HF output socket, and disconnect the frequency counter.
16. The HF signal seen on the oscilloscope screen is switched on for 250 msecs and then off for 250 msecs.
17. Control that the attack time of the HF signal is not more than 2 msecs, and that the decay time is not more than 3 msecs.
18. Set the testbox switch RF 50% DUTY CYCLE off and the testbox switch RF ON/OFF off.

If TELEX MODE is possible carry out the following points, if not go to the next section 3.5.3.3.

19. Connect the LF signal generator to the AF TO TX input on the testbox.
20. Adjust the LF signal generator output to 3Vpp/1600 Hz.
21. Select the emission mode TELEX on RE2100.
22. Set the testbox switch MIC.KEY on.
23. Control that the HF output shown on the oscilloscope is $4.0 \pm 0.5V_{pp}$.

3.5.3.3. Performance Check of Exciter Microphone Amplifier and LF Response

1. If only this chapter is performed, please start by carrying out the section 3.5.3.1. point 1, 2, and 3.
2. Select test programme SP-05-6 ($f_{TX} = 1.600$ kHz).
3. Set the testbox MIC-KEY on.
4. Set the LF signal generator frequency to 1Vpp/1600 Hz.
5. Adjust the LF signal generator frequency until the deflection seen on the oscilloscope is max. approx. 1600 Hz.
6. Adjust the oscilloscope gain until full deflection (8 div.) is seen on the screen.
7. Adjust the LF signal generator frequency to 350 Hz and to 2700 Hz and control that the deflection seen on the oscilloscope screen is above 4.0 div.
8. Set the LF signal generator frequency to 1.0Vpp/1000 Hz.
9. Adjust the oscilloscope gain until full deflection (8 div.) is seen on the screen.
10. Adjust the LF signal generator output level until the HF output level seen on the oscilloscope is approx. 7.5 div.
11. Control that the LF signal generator level at the input of the testbox is now 100 ± 50 mVpp.

3.5.3. PERFORMANCE CHECK OF EXCITER cont.:

3.5.3.4. Performance Check of Exciter Step Attenuator

1. If only this chapter is performed, please start by carrying out the section 3.5.3.1. point 1 and 2.
2. Select test programme SP-05-2.
3. Check that the stairs and staircase waveform seen on the oscilloscope screen has a continuous decreasing amplitude as shown below.

3.6. MODULE PERFORMANCE CHECK

GENERAL

A module performance check is intended to be used as an integral part of the trouble-shooting, because it gives the technician a chance to control the individual modules and parts of the circuit on each module.

The module performance check is divided into subsections, which correspond to the individual modules, and each of these subsections contains a number of check procedures.

The module performance check is carried out with all modules mounted in the HF SSB RE2100, and if a testbox is available, it should be used. The RE2100, the power supply, and the handset are all connected to the testbox as described in chapter 3.3. PROPOSAL FOR NECESSARY TEST EQUIPMENT.

If no testbox is available, it is possible to operate the RE2100 by connecting the power supply directly to the 25 pin connector, which is located at the back of the RE2100. The pin configuration for this connector is listed in chapter 2.3. ELECTRICAL CONNECTION AND ASSEMBLING. But it is only necessary to establish the following connections:

pin No. 10	-18V/0.2A
pin No. 11	+ 9V/0.5A
pin No. 12	+18V/0.8A
pin No. 5	GND

The handset is connected directly to the 9 pin connector at the back of the RE2100.

This chapter includes a number of measurements where a signal generator is needed. The output level of the generator is, in this manual, expressed in terms of the Electromotive Force (EMF), and it is measured in terms of the unit: dB/uV = 20 log(EMF/1uV), (dB above one microvolt).

The output level from signal generators in general is sometimes expressed in terms of the available power P_a , which is measured in terms of the unit: dBm = 10 log(P_a /1mW), (dB above one milliwatt). For this reason the conversion formulas between EMF and available power and vice versa are given here:

$$P_a \text{ (dBm)} = \text{EMF (dB/uV)} - 113 \text{ dB}$$

$$\text{EMF (dB/uV)} = P_a \text{ (dBm)} + 113 \text{ dB}$$

where P_a is the available power and EMF is the Electromotive Force of the generator.

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT

This chapter contains the following sections:

- 3.6.1.1. Check of Sensitivity (RX-Module)
- 3.6.1.2. Check of LO2 and Reinjection Signals
- 3.6.1.3. Check of Crystal Filters (2nd IF)
- 3.6.1.4. Check of 2nd IF Amplifier
- 3.6.1.5. Check of AGC Circuit
- 3.6.1.6. Check of Detector
- 3.6.1.7. Check of AF Filters
- 3.6.1.8. Check of Earpiece Amplifier
- 3.6.1.9. Check of Squelch Circuit

3.6.1.1. Check of Sensitivity (RX Module)

The sensitivity of the receiver unit is mainly determined by the Second Mixer because of its relatively large power gain of about 8 dB. It is therefore most likely that a degradation of the sensitivity is caused by the mixer; but be aware that this is not the only possible failure.

A degradation of the sensitivity could also be caused by a failure in the IF-amplifier, detector, audio frequency circuit, or simply by a missing local oscillator signal (LO2 or carrier reinjection).

To obtain a correct measurement of sensitivity, it is necessary to feed the generator signal through an impedance matching network as shown below.

Impedance matching between generator and receiver module.

1. Connect the generator to receiver module through the impedance matching network shown above.
2. Connect the voltmeter to earpiece output at testpoint TR2-1 for measuring the AC-voltage.
3. Turn the RE2100 on.
4. Choose generator frequency f_G and generator output level V_G as specified in point 6. Select the wanted Receiver Mode (SSB/AM).
5. Measure the signal to noise ratio SND/N at the earpiece output and check that it is above 20 dB. (see section 3.5.2.1., point 6 for instructions about how to measure SND/N).

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT cont.:

6.	Signal Generator			RE2100	
	f_G	$V_G(EMF)$	Mode	f_{RX}	Mode
	69.999.640 Hz	20 dB/uV	CW	no specification	J3E (SSB)
	70.000.640 Hz	35 dB/uV	AM mod. 30% with 1 kHz	no specification	H3E (AM)

3.6.1.2. Check of L02 and Reinjection Signals

The L02 signal is used in the mixing process from the 1st IF at 70.00064 MHz to the 2nd IF at 10.73152 MHz. The frequency of the L02 signal is 59.26912 MHz when receiving a H3E signal or J3E-USB signal. In J3E-LSB mode the frequency of the L02 signal is 80.73216 MHz.

The carrier reinjection signal is used in the detection of signals with a reduced carrier or signals without any carrier. The frequency of the carrier reinjection signal is 10.73152 MHz and is given by the TCX0.

1. Turn the RE2100 on and select J3E-USB mode.
2. To check the L02 signal, connect the diode probe across the resistor R188-1, which is located at the output of the L0 buffer at the Receiver Unit (module 1).
3. Check the measured DC voltage to be 3.3V $\pm$ 0.5V.
4. To check the reinjection signal connect a DC voltmeter through the diode probe to pin 8 at the detector IC (LM3189).
5. Check the measured DC voltage to be 300 mV $\pm$ 50 mV.

3.6.1.3. Check of Crystal Filters (2nd IF)

The selectivity of the second intermediate frequency is given by the crystal filters (SSB or AM filter), which form an important part of the overall receiver selectivity.

If the 2nd IF selectivity cannot fulfil the specified requirements, it is probably caused by a mistuning of the two crystal filters or by a mistuning of the 1st IF filter at 70 MHz.

The crystal filters are tuned by the trimming capacitor C18-1, which is located at the receiver unit. The adjustment procedure for this capacitor is described in section 3.7.1.3.

The 1st IF filter is tuned by three trimming coils and two transformers. The adjustment procedure for these components is described in section 3.7.1.1.

In this test of selectivity, the 6 dB bandwidth and the stop band attenuation is controlled. The test is performed by using variations in the level detector output voltage, which can be measured at testpoint TP1-1 in the AGC circuit. The voltage can be measured by using an analog multimeter, but it is easier to use a digital multimeter, because the variations in the level detector output voltage are relatively small (about 200 mV).

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT cont.:

SSB MODE

1. Connect the generator to the aerial socket at the front end unit (module 2).
2. Connect the voltmeter to testpoint TP1-1 for measuring the DC voltage at the level detector output.
3. Connect the counter to earpiece output at testpoint TP2-1.
4. Turn the RE2100 on.
5. Turn the RF gain control fully clockwise and make sure that the AGC is operative.
6. Choose generator frequency f_G , generator output level V_G and receiver frequency f_{RX} according to the table in point 20.
7. Make sure that J3E mode (SSB) is selected and that the AF signal frequency is approx. 1 kHz.
8. Wait 15 min. before proceeding, to temperature stabilize the receiver.
9. Turn off the AGC and adjust the manual RF GAIN Control to achieve a voltage of about 5 volt at testpoint TP1-1.
10. Finetune the receiver frequency by means of the arrow keys until maximum meter deflection, when measuring at testpoint TP1-1.
11. Readjust the manual RF GAIN to achieve a voltage of 5 volt at testpoint TP1-1.
12. To measure the 6 dB bandwidth, increase V_G by 6 dB and notice that the measured voltage will increase to about 14 volt.
13. Increase the receiver frequency by means of the upward arrow key until the voltage at testpoint TP1-1 is just about 5V.
14. Activate the clarifier function by pressing the <CLARIF> key and finetune the receiver frequency with the arrow keys until the voltage measured at testpoint TP1-1 is just above 5 volt. Now notice the receiver frequency in the display.
15. Deactivate the clarifier function by pressing the <CLARIF> key and decrease the receiver frequency by means of the downward arrow key until the measured voltage is just about 5V.
16. Repeat point 14.
17. Calculate the difference between the two frequencies found in points 14 and 16. This difference is equal to the 6 dB bandwidth, which must be above 2550 Hz.
18. To check the stopband attenuation, increase generator output level V_G by 20 dB relative to V_G in point 20.
19. Key-in the frequencies 1987.7 kHz and 1991.2 kHz and remember to turn off the AGC in each case. Control in both cases the DC voltage at testpoint TP1-1 to be below 5 volt.

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT cont.:

20.	Signal Generator			RE2100	
	f_G	$V_G(\text{EMF})$	Mode	f_{RX}	Mode
	1991 kHz	50 dB/uV	CW	1990 kHz	J3E (SSB)
	990 kHz	50 dB/uV	CW	990 kHz	H3E (AM)

AM MODE

21. Repeat points 1, 2 and 4-6.
22. Make sure that H3E mode (AM) is selected.
23. Repeat point 8-11.
24. Increase generator output level V_G by 6 dB.
25. To check the 6 dB bandwidth, key-in the frequencies 986,7 kHz and 993.3 kHz, and control in each case the voltage at testpoint TP1-1 to be above 5V. Remember in each case to turn off the AGC.
26. Increase generator output level V_G by 36 dB relative to V_G in point 20.
27. To check the stopband attenuation, key-in the frequencies 982,9 kHz and 997,1 kHz, and control in each case the voltage at testpoint TP1-1 to be below 5V. Remember in each case to turn off the AGC.

3.6.1.4. Check of 2nd IF Amplifier

In this test the gain of the 2nd IF amplifier is controlled by checking the threshold level of the Automatic Gain Control. This threshold level is defined in the figure below, where the AGC-characteristic is sketched.

AGC-characteristic used to define the sensitivity or threshold level of the AGC.

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT cont.:

Below the threshold level the input signal is too weak to be detected by the AGC circuit. The gain of the 2nd IF amplifier is then unregulated and the receiver output level will increase as 1:1 with increasing input level.

Above the threshold level the input signal is large enough to be detected by the AGC. The gain of the 2nd IF amplifier will then be regulated and the output from the receiver will idealistically be kept at a constant level. However, in practice the receiver output level will increase slightly with increasing input level, because a constant output level would require an infinite gain of the 2nd IF amplifier.

The performance of the AGC above the threshold level is checked by measuring the "flatness" of the AGC characteristic. This measurement is also included in the check procedure given below, because it is measured in the same manner as the threshold level.

The threshold level must, as indicated in the AGC characteristic, be less than the sensitivity level of the receiver to ensure correct function of the AGC. The threshold level is determined by the level detector and the open loop gain from the aerial input to the level detector input. To study this in more details, the simplified block diagram is used in the following description.

Simplified block diagram for the entire receiver.

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT cont.:

In the level detector, which is built-up around the transistor Q14-1, the base-emitter diode is used to convert the received AC signal to a DC signal. Thus the input voltage to the level detector is almost a constant and is equal to the diode cut-in voltage. The open loop gain from the aerial input to the level detector input must then be sufficiently high to produce the required peak voltage of about 0.65V with an input signal at the receiver sensitivity level.

In the simplified block diagram, the amplification from the aerial input to the level detector input is divided into four blocks, which are:

1. Front End Unit
2. 2nd Mixer plus 2nd IF Filter
3. 2nd IF Amplifier
4. AGC Amplifier.

If the receiver does not pass the test of the threshold level given below, it is probably caused by a loss of gain in one of the four blocks.

The gain of the Front End Unit can be controlled directly by the test procedure given in the section 3.6.2.5., while the gain of the 2nd mixer and the 2nd IF filter can only be controlled indirectly by the sensitivity test of the RX module given in section 3.6.1.1.

The gain of the AGC amplifier can be controlled by measuring the detector output level, which must be almost constant from one module to another, because of the rectifying diode in the level detector. To control the detector output level, use the check procedure given in section 3.6.1.6.

If the Front End Unit, the 2nd mixer and 2nd IF filter, and the AGC amplifier all perform as expected, the 2nd IF amplifier must finally be examined. The problem may be solved by adjusting the reference voltage V_{REF} in the AGC circuit. The adjustment is performed by the trimming resistor R203-1 and is described in section 3.7.1.4.

1. Connect the generator to the aerial socket at the front end unit (module 2).
2. Connect the voltmeter to testpoint TP2-1 for measuring the AC voltage at the earpiece output.
3. Turn the RE2100 on and turn the RF gain control fully clockwise.
4. Choose generator frequency f_G , generator output level V_G , and receiver frequency f_{RX} according to point 9.
5. Measure the signal to noise ratio SND/N at the earpiece output (see section 3.5.2.1., point 6 for instructions about how to measure SND/N). If the signal to noise ratio SND/N is different from 20 dB, the generator output level must be adjusted until this value is obtained.
6. Notice the earpiece output at testpoint TP2-1.
7. To control the threshold level of the AGC, increase the generator output level V_G by 20 dB and control that the earpiece output level does not increase by more than 2 dB relative to the level measured in point 6.
8. To control the flatness of the AGC, increase the generator output level V_G by 50 dB so the total increase is 70 dB. Control that the earpiece output level does not increase by more than 3 dB relative to the level measured in point 6.

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT cont.:

9.	Signal Generator			RE2100	
	f_G	$V_G(\text{EMF})$	Mode	f_{RX}	Mode
	1991 kHz	7dB/uV	CW	1990 kHz	J3E (SSB)

3.6.1.5. Check of AGC Circuit

In this test the attack and decay time of the automatic gain control is controlled by measuring the step response of the AGC circuit.

In J3E mode (SSB) the attack time is determined by the resistors R89-1, R91-1 and capacitor C72-1, while the decay time is determined by R63-1 and C69-1.

In H3E mode (AM) the attack time and decay time are determined by R89-1, R91-1 and C71-1.

The measurement of step response is performed by a sudden increment or decrement of the RF input level. This step in input level is obtained by toggling the RX mute relay, which is located at the front end unit. The relay is controlled by two different service programmes.

The step response will be displayed on an oscilloscope, which with advantage may be a storagescope.

1. Connect the generator to aerial socket at the front end unit (module 2).
2. Connect the oscilloscope to testpoint TP3-1 for measuring the AGC voltage and select AC coupling.
3. Connect a probe from testpoint TP4-2 (collector of transistor Q01-2, located at front end unit) to the external trigger input on the oscilloscope.
4. Select external trig source, DC trig mode, and negative slope trig.
5. Turn the RE2100 on and turn the RF gain control fully clockwise.
6. Choose generator frequency and generator output level V_G as specified in point 12.
7. In points 8-10 the AGC responses are measured with the oscilloscope and they must be similar to the responses shown below.
NOTE! It may be necessary to adjust trig level to obtain an image on the oscilloscope.
8. To measure the attack time in J3E mode, select service programme SP-04-6.
9. To measure the decay time in J3E mode, select service programme SP-04-6 and change the setting of the oscilloscope.
NOTE! To change service programme press <STOP>.
10. To measure the attack and decay time in H3E mode, select service programme SP-04-7 and change the setting of the oscilloscope. Select positive slope trig.
11. Press <TUNE> to leave service programme mode.

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT cont.:

12.

Signal Generator			RE2100	
f_G	$V_G(\text{EMF})$	Mode	f_{RX}	Mode
1991 kHz	70 dB/uV	CW	1990 kHz	J3E (SSB)
1991 kHz	70 dB/uV	AM mod. 30% with 1 kHz	1991 kHz	H3E (AM)

The RE2100 is automatically set by the service programmes.

AGC Step Responses.

3.6.1.6. Check of Detector

In this section the audio frequency output level and distortion from the detector are controlled.

The output level from the detector is determined by the input level to the detector and by the detector itself.

The input level to the detector is given by the base-to-emitter voltage of transistor Q14-1 divided by the voltage gain of the AGC amplifier, which is built-up around transistor Q16-1.

1. Connect the generator to the aerial socket at the front end unit (module 2).
2. Connect the voltmeter and a distortion meter to detector output at U06, pin 6.

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT cont.:

3. Turn the RE2100 on, and turn the RF gain control fully clockwise.
4. Choose generator frequency f_G , generator output level V_G , and receiver frequency f_{RX} according to point 6.
5. Measure the AF output level and distortion at detector output and control the result by comparing it to the values given in point 6.

6.	Signal Generator			RE2100		Detector Output	
	f_G	$V_G(\text{EMF})$	Mode	f_{RX}	Mode	Level	Distortion
	1991 kHz	70dB/uV	CW	1990 kHz	J3E(SSB)	600 mV _{RMS} -800 mV _{RMS}	1.5%
	1991 kHz	70dB/uV	AM-mod. 30% with 1 kHz	1991 kHz	H3E(AM)	75mV _{RMS} -95mV _{RMS}	2%

3.6.1.7. Check of AF Filters

The audio frequency selectivity is controlled by measuring the overall selectivity of the receiver.

If the measured data cannot fulfil the specified requirements, it is necessary to control the 2nd IF selectivity before any conclusion can be made.

SSB MODE

1. Connect the generator to the aerial socket at the front end unit (module 2).
2. Connect the voltmeter and the counter to testpoint TP2-1 (earpiece output).
3. Turn the RE2100 on and turn the RF gain control fully clockwise.
4. Choose generator frequency f_G , generator output level V_G , and receiver frequency f_{RX} according to point 11.
5. Make sure that J3E mode (SSB) is selected, that AGC is on, and that the AF signal frequency is approx. 1 kHz.
6. Finetune the receiver frequency by means of the arrow keys until maximum meter deflection when measuring at testpoint TP2-1.
7. Notice the AC voltage at testpoint TP2-1.
8. Turn the AGC off and adjust the RF gain control to achieve the output level found in point 7.
9. To check the 6 dB bandwidth, choose the generator frequencies 1990.35 kHz and 1992.70 kHz and control in each case the AC voltage at testpoint TP2-1 not to decrease more than 6 dB relative to the value measured in point 7.

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT cont.:

10. To check the stopband attenuation, choose the generator frequency 1993,1 kHz and control the AC voltage at testpoint TP2-1 to decrease more than 20 dB relative to the value measured in point 7.

11.	Signal Generator			RE2100	
	f_G	$V_G(\text{EMF})$	Mode	f_{RX}	Mode
	1991 kHz	70 dB/uV	CW	1990 kHz	J3E (SSB)
	1991 kHz	70 dB/uV	AM mode 30% with 1 kHz	1991 kHz	H3E (AM)

AM MODE

12. Repeat point 1-4.
13. Make sure that H3E mode (AM) is selected, that AGC is on, and that the AF signal frequency is approx. 1 kHz.
14. Finetune the receiver frequency by means of the arrow keys until maximum meter deflection at testpoint TP2-1.
15. Notice the AC voltage at testpoint TP2-1.
16. To check the 6 dB bandwidth, change the modulation frequency of the generator to 100 Hz and 3000 Hz, and control in each case the AC voltage at testpoint TP2-1 not to decrease more than 6 dB relative to the value measured in point 15.
17. To check the stopband attenuation, change the modulation frequency of the generator to 6 kHz and control the AC voltage at testpoint TP2-1 to decrease more than 40 dB relative to the value measured in point 15.

3.6.1.8. Check of Earpiece Amplifier

The purpose of this test is to control the earpiece amplifier, which is built-up around the integrated circuit U07. If the earpiece output level is outside the specified range, it is necessary to re-adjust the trimming resistor R52-1, which is located at the receiver unit. If it is not possible to adjust the output level to be within the specified range, it is necessary to control the detector output level before any conclusion can be made.

1. Connect the generator to the aerial socket at the front end unit (module 2).
2. Connect the voltmeter and the distortion meter to earpiece output at testpoint TP2-1.
3. Turn the RE2100 on and turn the RF gain control fully clockwise.
4. Choose generator frequency f_G , generator output level V_G , and receiver frequency f_{RX} according to point 7.

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT cont.:

5. Measure the earpiece output level at testpoint TP2-1 and control the result to be within the range $0.7V_{RMS}$ - $0.9V_{RMS}$.
6. Measure the earpiece output distortion at testpoint TP2-1 and control the result to be less than 1.5%.

7.

Signal Generator			RE2100	
f_G	$V_G(EMF)$	Mode	f_{RX}	Mode
1991 kHz	70dB/uV	CW	1990 kHz	J3E (SSB)

3.6.1.9. Check of Squelch Circuit

The squelch circuit in the RE2100 is voice activated and it works in principle by detecting deviations in the frequency of the received signal. This relative complex squelch function is implemented by means of four separate blocks, which are:

1. Limiting amplifier
2. Frequency to Voltage Converter
3. Voltage Change Detector
4. Hold Circuit

The output voltage from the Hold Circuit is sensed by the microprocessor and this unit is then controlling the analog switch, which is used to mute the audio frequency output.

In the check procedure given below only the analog part of the squelch is controlled and if this is performing as expected, a failure may be caused by the microprocessor or the connection cabling.

1. Connect the generator to the aerial socket at the front end unit.
2. Connect a handset or loudspeaker to the testbox or directly to the RE2100.
3. Turn the RE2100 on and turn the RF gain control fully clockwise.
4. Choose generator frequency f_G ; generator output level V_G , and receiver frequency f_{RX} as specified in point 15.
5. Switch off the squelch and make sure that you now hear a 1600 Hz tone.
6. To control the limiting amplifier connect the oscilloscope to the output of the operational amplifier U02/1, pin 1. Control the measured signal to be squarewave with a frequency of 1600 Hz and an amplitude of about 13Vpp.
7. To control the frequency to voltage converter, connect the voltmeter to the output of the operational amplifier U02/4, pin 14 and control the DC voltage to be about 7V.
8. Increase the generator frequency with 1 kHz and control the DC voltage at U02/4, pin 14, to increase to about 11V. Decrease the generator frequency with 2 kHz ($f_G = 1990.6$ kHz) and control the DC voltage to decrease to about 4V.

3.6.1. MODULE PERFORMANCE CHECK OF RECEIVER UNIT cont.:

9. To control the voltage change detector, connect the oscilloscope to the output of the operational amplifier U01/4, pin 14. Select DC trig mode and positive slope trig.
10. Change the generator frequency with ± 1 kHz relative to the frequency specified in point 15 and control in each case the voltage change detector to generate an impulse with a magnitude of about 13V and a duration of about 350 msec.
11. To control the Hold Circuit, choose the generator frequency specified in point 15, and switch on the squelch.
12. Connect the voltmeter to the output of the operational amplifier U01/1, pin 1.
13. Decrease the generator frequency with 1 kHz and control the DC voltage at U01/1, pin 1 to be about 13V. You will now hear a 600 Hz tone in your handset or loudspeaker.
14. Control the DC voltage at U01/1, pin 1 to fall to 0V after a time period of about 10 secs and control that the audio frequency output is muted.

15.

Signal Generator			RE2100	
f_G	$V_G(\text{EMF})$	Mode	f_{RX}	Mode
1991.6 kHz	70 dB/uV	CW	1990 kHz	J3E (SSB)

3.6.2. MODULE PERFORMANCE CHECK OF FRONT END UNIT

This chapter contains the following sections:

- 3.6.2.1. Check of Sensitivity (RE2100)
- 3.6.2.2. Check of Front End Gain
- 3.6.2.3. Check of Mute and RX/TX Switch
- 3.6.2.4. Check of Selection Circuit for Pre-Filters
- 3.6.2.5. Check of L01 Signal and Buffer

3.6.2.1. Check of Sensitivity (RE2100)

The sensitivity of the entire receiver can in J3E mode be calculated from the following equation:

$$\text{SENS} \approx 10 \log \left(F_{\text{front}} + \frac{F_{\text{RX}} - 1}{G_{\text{front}}} \right) - 7 \text{ dB} \quad (\text{dB/uV})$$

where the following figures shall be taken as typical values:

- $F_{\text{front}} = 5.2 \approx 7.2 \text{ dB}$: Noise factor and figure for Front End
- $F_{\text{RX}} = 6.3 \approx 8.0 \text{ dB}$: Noise factor and figure for Receiver
- $G_{\text{front}} = 0.5 \approx -3.0 \text{ dB}$: Available power gain for Front End

The equation is only valid when using a single tone SSB test signal, which produces a signal to noise ratio of 20 dB at the receiver output, and when using a signal generator with an impedance of 50 ohm.

From the figures it can be seen that both the Front End Unit and the Receiver Unit are determining the sensitivity level.

To exclude the receiver unit, it is necessary to check the sensitivity level of this unit separately, which can be done by means of the check procedure described in section 3.6.1.1.

The available power gain, G_{front} , of the Front End Unit can be controlled by the check procedure given in the next section (3.6.2.2.).

The check procedure in this section is especially useful to control the insertion loss of the six parallel coupled bandpass filters, which are used as pre-filters in the Front End Unit. If the sensitivity is poor in only one band, it is very likely that the corresponding filter or the filter selection circuit has a failure.

The filter selection circuit can be checked by means of the check procedure given in section 3.6.2.3.

1. Connect the generator to the aerial socket through the 50 ohm impedance matching network shown in chapter 3.3. PROPOSAL FOR NECESSARY TEST EQUIPMENT.
2. Connect the voltmeter to the earpiece output at testpoint TP2-1 for measuring the AC voltage.
3. Turn the RE2100 on.

3.6.2. MODULE PERFORMANCE CHECK OF FRONT END UNIT cont.:

4. Choose generator frequency f_G , generator output level V_G , and Receiver frequency f_{RX} as specified in point 6.
5. Measure the signal to noise ratio SND/N at the earpiece output and check that it is above 20 dB. (See section 3.5.2.1., point 6 for instructions about how to measure SND/N).

6.

Pre-filter number	Signal Generator		RE2100		
	f_G (kHz)	V_G (EMF)	Mode	f_{RX}	Mode
1	101	18 dB/uV	CW	100	J3E USB
	385	10 dB/uV		384	
2	386	10 dB/uV		385	
	1600	8 dB/uV		1599	
	995	23 dB/uV	AM 30% with 1 kHz	995	H3E
3	1601	8 dB/uV	CW	1600	J3E USB
	4500	8 dB/uV		4499	
	2182	23 dB/uV	AM 30% with 1 kHz	2182	H3E
4	4501	8 dB/uV	CW	4500	J3E USB
	9000	8 dB/uV		8999	
5	9001	8 dB/uV		9000	
	18000	9 dB/uV		17999	J3E USB
	12352	8 dB/uV		12353	
6	18001	9 dB/uV		18000	J3E USB
	29981	9 dB/uV		29980	
	18373	23 dB/uV	AM 30% with 1 kHz	18373	H3E

NOTE! The signal levels given in point 6 are referring to the output of the 50 ohm impedance matching network, which has an EMF insertion loss of 20 dB. To obtain the setting of the signal generator, the insertion loss of 20 dB must be added to the levels given in point 6.

3.6.2.2. Check of Front End Gain

In this test the available power gain of the Front End Unit is controlled. The gain is determined by an indirect measurement and it is therefore necessary to correct the measured data afterwards.

3.6.2. MODULE PERFORMANCE CHECK OF FRONT END UNIT cont.:

In the test procedure given below, the input and output levels of the Front End Unit are measured by means of the diode probe. To avoid mistuning of the 70 MHz output filter, because of the capacitive loading introduced by the diode probe, it is necessary to measure the output level through a voltage divider. The Front End Unit must then be terminated as shown in the figures below, where the wanted loading impedance of 800 ohm is realized with a voltage divider consisting of a resistor of 750 ohm in series connection with a resistor of 50 ohm.

Termination of the Front End Unit for measurement of the available power gain. The termination is realized at the Receiver Unit (module 1).

The resistor R185-1 must be disconnected as shown above, before the termination of the Front End Unit can be implemented.

1. Terminate the Front End Unit as shown in the figures above.
2. Turn the RE2100 on.
3. Choose generator frequency f_G , generator output level V_G , and receiver frequency f_{RX} as specified in point 10.
4. Connect the diode probe across the 50 ohm resistor in the Front End terminating network (see figure above).
5. Notice the diode probe voltage.
6. Connect the diode probe across the neon lamp at the input of the front end unit.

3.6.2. MODULE PERFORMANCE CHECK OF FRONT END UNIT cont.:

7. Adjust the signal generator level V_G until the diode probe voltage is equal to the value measured in point 5.
8. Calculate the difference between the signal generator level used in point 3 and the level found in point 7.
9. The available power gain of the front end unit can now be calculated by means of the equation

$$G_{\text{front}} = 12 \text{ dB} - \Delta V_G$$

where ΔV_G is the difference in generator level found in point 8. The gain should be $-2 \text{ dB} \pm 2 \text{ dB}$.

10.

Signal Generator			RE2100	
f_G	V_G (EMF)	Mode	f_{RX}	Mode
1991 kHz	120 dB/uV	CW	1990 kHz	J3E (SSB)

3.6.2.3. Check of Mute and RX/TX Switch

The mute relay RE01-2 is used for external mute functions and for protection of the Front End Unit, when the RE2100 is switched off. The mute function is checked by toggling the relay RE01, which is done by means of the service programme SP-04-6.

The RX/TX relay RE02-2 is used for switching between receiver and transmitter mode. The RX/TX relay is normally in the non-activated state, which corresponds to RX-mode. To obtain the TX-mode, the relay must be activated. This can only be done by means of a service programme, when the RE2100 is disconnected from the transmitter T2130.

1. To check the mute relay, connect the signal generator to the aerial socket at the Front End Unit.
2. Choose the generator frequency $f_G = 1991 \text{ kHz}$ and the generator level, $V_G = 70 \text{ dB/uV}$.
3. Select the service programme SP-04-6 and control the number of lighted LED's in the signal strength meter to change between about five and eight with a time interval of about 2 secs.
NOTE! Make sure that the signal strength meter is correctly adjusted.
4. To check the RX/TX relay connect a handset to the RE2100 for keying the exciter. If a testbox is available, this can be used instead.
5. Connect the voltmeter through diode probe to the aerial socket at the front end unit.
6. Select the service programme SP-05-0 and key the exciter.
7. Control the DC-voltage measured through the diode probe at the aerial socket to be $6V \pm 1V$.
8. To leave service programme mode press <TUNE>.

3.6.2. MODULE PERFORMANCE CHECK OF FRONT END UNIT cont.:

3.6.2.4. Check of Selection Circuit for Pre-Filters

The switching between the pre-filters is controlled from the microprocessor through the shift register J01-2 and six operational amplifiers which are included in the two IC's U02-2 and U03-2.

1. Key-in the receiver frequencies and control the DC-voltage at the output of U02-2 and U03-2 to be in accordance with the table in point 2.

2.

Receiver Frequency (kHz)	U02				U03	
	pin 1	pin 7	pin 8	pin 14	pin 1	pin 7
196	0V	0V	0V	0V	0V	13V
785	0V	0V	0V	0V	13V	0V
2683	0V	0V	0V	13V	0V	0V
6364	0V	0V	13V	0V	0V	0V
12728	0V	13V	0V	0V	0V	0V
23238	13V	0V	0V	0V	0V	0V

3.6.2.5. Check of L01 Signal and Buffer

In this test the level of the L01 signal at the output of the buffer is controlled.

The L01 signal is used in the mixing process from the receiver frequency f_{RX} to the 1st IF at 70,000,640 MHz.

The frequency of the L01 signal can be varied from 70 MHz to 100 MHz and is determined by the equation:

$$f_{L01} = f_{RX} + f_{IF1} = f_{RX} + 70,000,640 \text{ MHz}$$

where f_{RX} is the receiver frequency.

1. Connect the voltmeter through the diode probe across the coil L41-2.
2. Turn the RE2100 on.
3. Key-in the receiver frequency 2182 kHz.
4. Control the measured DC voltage to be 7.5V $\pm$ 1V.

3.6.3. MODULE PERFORMANCE CHECK OF SYNTHESIZER UNIT

This chapter contains the following sections:

- 3.6.3.1. Check of TCXO
- 3.6.3.2. Check of PLL1
- 3.6.3.3. Check of PLL2

3.6.3.1. Check of TCXO

The TCXO signal is used as reference frequency in both PLL1 and PLL2, and it is also used as carrier injection signal for both transmitter and receiver.

1. Turn the RE2100 on.
NOTE! The RE2100 must be on for at least 15 minutes before the check is carried out.
2. Connect the counter to TP4-3 through passive probe.
3. Check the frequency on TP4-3 to be 10.731520 MHz ± 1 Hz.

3.6.3.2. Check of PLL1

The PLL1 consists of four independent VCO's, which together cover the whole frequency band from 70 MHz to 100 MHz.

1. Turn the RE2100 on.
2. Connect the voltmeter to TP1-3.
3. Connect the counter to TP3-3.
4. Key-in the RX frequency and check the DC-voltage on TP1-3 and the frequency on TP3-3 to be in accordance with table in point 5.
- 5.

RX-frequency	Frequency on TP3-3	Voltage on TP1-3
7499.0	77.49964 MHz ± 10 Hz	-11.0V ± 1 V
14999.0	84.99964 MHz ± 10 Hz	-11.0V ± 1 V
22499.0	92.49964 MHz ± 10 Hz	-11.0V ± 1 V
29999.0	99.99964 MHz ± 10 HZ	-11.0V ± 1 V

6. Key in the RX-frequency and check the DC-voltage on TP1-3 and the frequency on TP3-3 to be in accordance with point 7.

3.6.3. MODULE PERFORMANCE CHECK OF SYNTHESIZER UNIT cont.:

7.

RX-frequency	Frequency on TP3-3	Voltage on TP1-3
100.0	70.10064 MHz ± 10 Hz	-3.0V ± 1.0 V
7500.0	77.50064 MHz ± 10 Hz	-3.0V ± 1.0 V
15000.0	85.00064 MHz ± 10 Hz	-3.0V ± 1.0 V
22500.0	92.50064 MHz ± 10 Hz	-3.0V ± 1.0 V

8. Select RX-frequency 2225.4 kHz and measure the frequency on TP3-3.

9. Select RX-frequency 2075.3 kHz and measure the frequency on TP3-3, then subtract it from the frequency measured in check point 8. The result must be 150.100 kHz ± 2 Hz.

10. Connect the voltmeter to TP3-3 through diode probe.

11. Select RX-frequency and check the voltage on TP3-3 to be in accordance with point 12.

12.

RX-frequency	Voltage on TP3-3
3750.0	>0.8 Volt
11250.0	>0.8 Volt
18750.0	>0.8 Volt
26250.0	>0.8 Volt

13. Connect the voltmeter to TP2-3 through diode probe.

14. Select service programme SP-04-5 as described in this manual, section 3.10.1. and check the voltage on TP2-3 to be above 0.8 Volt.

3.6.3.3. Check of PLL2

The PLL2 consists of two independent VCO's and is capable of delivering two different signals with the frequencies 59.26912 MHz and 80.73216 MHz.

1. Turn the RE2100 on.

2. Connect the voltmeter to TP5-3.

3. Connect the counter to TP7-3.

4. Select receiver mode and check the DC-voltage on TP5-3 and the frequency on TP7-3 to be in accordance with point 5.

5.

Mode	Frequency on TP7-3	Voltage on TP5-3
J3E	59.26912 MHz ± 10 Hz	-6.5V ± 0.5 V
LSB	80.73216 MHz ± 10 Hz	-6.5V ± 0.5 V

3.6.3. MODULE PERFORMANCE CHECK OF SYNTHESIZER UNIT cont.:

6. Connect the voltmeter to TP7-3 through diode probe.
7. Check the voltage on TP7-3 to be in accordance with table 8.

8.

Mode	Voltage on TP7-3
J3E	>0.8 Volt
LSB	>0.8 Volt

9. Connect the voltmeter to TP6-3 through diode probe.
10. Select service programme SP-04-5 as described in this manual, section 3.10.1., and check the voltage on TP6-3 to be above 0.8 Volt.

3.6.4. MODULE PERFORMANCE CHECK OF EXCITER UNIT

This chapter contains the following sections:

- 3.6.4.1. Check of Compressor and AF Limiter
- 3.6.4.2. Check of Carrier Limiter Amplifier
- 3.6.4.3. Check of Modulator
- 3.6.4.4. Check of SSB Filter
- 3.6.4.5. Check of RF Limiter and Carrier Insertion
- 3.6.4.6. Check of Step Attenuator
- 3.6.4.7. Check of 70 MHz IF and LO Injection

Any value, which differs too much from the values given in this chapter should lead to an adjustment of the circuit in question. Please, see chapter 3.7.3. ADJUSTMENT PROCEDURE FOR EXCITER UNIT

How to select service programmes is described in the chapter 3.10.

3.6.4.1. Check of Compressor and AF Limiter

1. Connect a tone generator (1000 Hz) to the testbox at the BNC-socket "AF to TX". If a testbox is not available, connect the tone generator directly to the handset plug on the RE2100 (to J03-2, pin 4). Connect it with a capacitor 22 μ F/25V because of the DC voltage on the microphone terminal.
2. Connect a scope probe to Q04-4 emitter (TP1-4).
3. Select service programme SP-05-1 and select J3E mode.
4. Adjust the tone generator output voltage from a minimum until the level at the scope is just constant. This limitation must happen at approx. 0.1Vpp measured at the handset plug J03-2, pin 4.
5. Check that the voltage at Q04-4 (TP1-4) stays approx. at the same level when increasing the tone generator 20 dB to 1Vpp.
6. Select service programme SP-05-0.
7. Connect scope probe to R07-4 and read approx. 0.5 Vpp (tune tones).
8. Connect scope probe to Q04-4 emitter (TP1-4).
9. Connect R34-4 (TP7-4) to ground (chassis). That is a short-circuit of R34-4, which means that the signal exceeds the cutting level.
10. Adjust the scope to full deflection (8 div).
11. Disconnect the grounding of R34-3 and read the peak-peak deflection to 6.9 div. $\pm$ 0.3 div.

3.6.4. MODULE PERFORMANCE CHECK OF EXCITER UNIT cont.:

3.6.4.2. Check of Carrier Limiter Amplifier

1. Select service programme SP-05-0 and press handset key.
2. Connect a scope probe to J01-4 and measure the carrier injection to approx. 0.1Vpp.
3. Connect scope probe to the connection between R93-4 and C75-4 (TP2-4) and read the voltage to 1,55Vpp $\pm 0.1V$.

3.6.4.3. Check of Modulator

1. Select service programme SP-05-0 and press handset key.
2. Connect a scope probe to U06-4, pin 10 and read approx. 0.17Vpp.
3. Connect scope probe to U06-4, pin 1 and read approx. 0.75 Vpp.
4. Connect scope probe to the connection between C66-4 and C67-4 (TP3-4) and read the voltage to 6.6 Vpp $\pm 0.3V$.

3.6.4.4. Check of SSB Filter

1. Connect a tone generator to the testbox at the .BNC-socket "AF to TX". If a testbox is not available, connect the tone generator directly to the handset plug on the RE2100 (to J03-2, pin 4). Connect it with a capacitor 22 μF /25V because of the DC voltage on the microphone terminal. Set the tone generator output level to 0.3 Vpp.
2. Select service programme SP-05-1 and select J3E mode on the keyboard.
3. Press handset key.
4. Connect a scope probe to Q19-4 emitter (TP4-4).
5. Control of SSB filter response is carried out by changing the frequency of the tone generator and controlling the reading on the scope. Max. permissible ripple is 2 dB in the frequency range 500 Hz to 2500 Hz and the -6 dB frequency is approx. 350 Hz and 2700 Hz.

3.6.4.5. Check of RF Limiter and Carrier Insertion

1. Select service programme SP-05-0 and press handset key.
2. Connect the scope probe to Q19-4 emitter (TR4-4) and read the voltage to approx. 1.5Vpp.
3. Short-circuit R34-4 (TP7-4) to ground, and the signal seen on the scope is now cut.
4. Adjust the scope until full deflection (8 div) of the cut signal is seen on the scope screen.
5. Disconnect the grounding of R34-4 and read on the scope the peak-peak voltage to be 7.2 div. ± 0.2 div.

3.6.4. MODULE PERFORMANCE CHECK OF EXCITER UNIT cont.:

6. Adjust the scope until full deflection of the signal is seen on the scope screen.
7. Select service programme SP-05-1 and press handset key.
8. Select H3E mode on the keyboard.
9. Check on the scope that the signal is 4.4 div. ± 0.3 div.
10. Select R3E mode on the keyboard.
11. Check on the scope that the signal is 1.2 div. ± 0.2 div.

3.6.4.6. Check of Step Attenuator

1. Select service programme SP-05-0 and press handset key.
2. Connect a scope probe to R169-4 (TP5-4) and read the signal to 0.55Vpp ± 0.05 V.
3. In order to check the linearity of the step attenuator, please see section 3.7.3.6. points 6-9.

3.6.4.7. Check of 70 MHz IF and L0 Injection

1. Select service programme SP-05-3 and H3E mode.
2. Press handset key.
3. Place a diode probe on top of Q17-4 and read approx. 0.95V.
4. Select service programme SP-05-1 and H3E mode and press handset key.
5. Place the diode probe on top of Q17-4 and read approx. 1.25V.
6. Select service programme SP-05-0 and press handset key.
7. Place a diode probe on J02-4 and read approx. 1.4V.
8. Place the diode probe on top of Q17-4 and read approx. 1.75V.
9. Place the diode probe on J04-4 and read 1.8V.
10. Place the diode probe on top of Q24-4 and read approx. 13.5V.

3.6.5 PERFORMANCE CHECK OF MICROPROCESSOR MODULE 5.

GENERAL

To execute a performance check of a microprocessor unit, keyboard unit and display unit (module 5, 6 and 7) it is necessary to dismantle the cover and remove the 2 PCB covers on module 5. Disconnect the BNC and 25 poles D-connector to T2130. Connect an external +18V power supply at J03 pin 12 or pin 24, an external -18V power supply at J03 pin 10 and an adjustable +9V power supply at J03 pin 11 or pin 23.

CHECK OF ON BOARD POWER SUPPLY

Connect a voltmeter between ground and anode of D02. Control the voltage to $> 7.0V$. Normally $9.0V$.

Connect a voltmeter between ground and U15 pin 2. Control the voltage:
 $4.75V < +5VA < 5.25V$.

Connect a voltmeter between ground and U17 pin 3. Control the voltage:
 $4.50V < +5VB < 5.50V$.

Connect a voltmeter between ground and U18 pin 3. Control the voltage:
 $-4.50V > -5VB > -5.50V$.

CHECK OF MICROPROCESSOR

Control of Strap in P02.

If the strap is connected between pin 1 and pin 2, the microprocessor will read the programme from internal ROM. This is only used if the microprocessor U07 is mask programmed. In that case the ROM U06 will not be mounted. If the strap is connected between pin 2 and pin 3, the microprocessor will read the programme from U06.

Control of Strap in P03.

If the strap is connected between pin 1 and pin 2, the microprocessor will run in service programme mode. The display will read out "SP- ". Look up the description of Service Programmes in chapter 3.10. If the strap is connected between pin 2 and pin 3, the microprocessor will run the normal programme.

Control of the Internal Clock Frequency.

Connect a frequency counter to U07 pin 64. The frequency must be $2000 \text{ kHz} \pm 16.0 \text{ kHz}$ ($X\text{-tal}/4$).

CHECK OF EXTERNAL ROM

If the microprocessor is strapped to external ROM, control the strap in P01. If the strap is connected between pin 1 and pin 2, the device (ROM) in socket U06 must be a 256 Kbyte type (e.g. 27C256). If the strap is connected between pin 2 and pin 3, the device (ROM) in socket U06 must be a 128 Kbyte type (e.g. 27C128).

3.6.5. PERFORMANCE CHECK OF MICROPROCESSOR MODULE 5 cont.

CHECK OF POWER LOW CIRCUIT AND WATCH DOG CIRCUIT

Control of Power Low Circuit

Adjust the 9V external power supply to 9.0V. When the power is switched on, control that the display will read out "Error20" (there is no connection to T2130). Press the distress key (2182), and the display will now read out "_2182.0". Turn the 9V power supply down slowly and control the power voltage. When the display reads out "Error00" (the 9V power supply is too low) the power supply must be approx. 7.0V.

Control of Watch Dog Circuit.

Adjust the 9V power supply to approx. 9.0V. Connect an oscilloscope to U15 pin 6 and control that the square wave seen has a 5.0V +/- 0.5V amplitude, that the duty cycle is 50%, and that the frequency is one of 3 possible:

1. 15 Hz. Standard after power is switched on.
2. 20 Hz. Standard for Test Alarm mode.
3. 50 Hz. Standard for Scan Run mode.

Connect a test wire between ground and U15 pin 6. Control that the microprocessor will start a reset cycle after every 1.6 s. (the display will flash an "Error20". Disconnect the test wire again and control that the microprocessor will stop the reset cycle.

CHECK OF BAUD RATE GENERATOR

Connect a frequency counter to U02 pin 9. The frequency will be a 26th part of the internal clock frequency (normally 76.923 kHz +/- 600 Hz.), and the duty cycle is 50%.

CHECK OF TUNE/ALARM TONE GENERATOR

Press the digits 0 and 1 at same time. The equipment will now be in Quick Service mode and the display will show "SP- ".

3.6.5. PERFORMANCE CHECK OF MICROPROCESSOR MODULE 5 cont.

Control of Tune Tone

Connect an oscilloscope to emitter of Q01 and press the digits 0-2-0 and ENT. The display will show "SP-02-0". Control that the wave form seen is approx. equal to the one shown below. Press STOP to stop the tone.

Tune Tone Test.

Control of Alarm Tone

Connect a frequency counter to emitter of Q01 and press the digits 0-2-2 and ENT. The display will show "SP-02-2". Control the frequency to 1300 Hz $\pm$ 1.5%. Press STOP to stop the tone. Then press the digits 0-2-3 and ENT. The display will show "SP-02-3". Control the frequency to 2200 Hz $\pm$ 1.5%. Press STOP to stop the tone. Press TUNE/CLARIF to exit the Quick Service mode.

CHECK OF DISTRESS DRIVER

Press "2182" (Distress), the RX- and TX-display will show " 2182.0". Connect a voltmeter to collector of Q03 and control the voltage to be 14.8V $\pm$ 1.5V. Key-in a new TX-frequency and control that the voltage will go down to approx. 0V.

CHECK OF METER AMPLIFIER

Connect a test wire between ground and J03 pin 15. Connect a voltmeter between ground and U12 pin 7. Control the voltage to 600 mV $\pm$ 50mV. Connect the test wire between J03 pin 15 and U17 pin 3. Control the voltage on U12 pin 7 to 3.6V $\pm$ 250mV.

CHECK OF SPI DATA BUS

Press "2182" (Distress), the RX- and TX-display will show " 2182.0". Then press CH-1-ADD and 2-ADD, the distress frequency is now programmed into channel 1 and 2. Then press SC-8-ENT. If the scanning is started, press STOP and delete the channels for scan programme No. 8 until the display shows "CH-no". Press 1-ADD-2-ADD-ENT, channel 1 and channel 2 are now programmed in scan programme No. 8, and the receiver will now scan channel 1 and channel 2 with the same frequency. If the scanner stops at the channel then disconnect the antenna plug.

3.6.5. PERFORMANCE CHECK OF MICROPROCESSOR MODULE 5 cont.

Check of SPI Data

Connect an oscilloscope channel A to U10 pin 4 and channel B to U10 pin 10. Set TB=50 uS. Control that the two wave forms are the same. The voltage is 5Vpp +/-0.5V.

Check of SPI Clock

Connect an oscilloscope channel A to U10 pin 2 and channel B to U10 pin 12. Set TB=50 uS. Control that the two wave forms are the same. The voltage is 5Vpp +/-0.5V. The clock period is 26 uS.

Check of Timing Between SPI Data and Clock

Connect an oscilloscope channel A to U10 pin 2 and channel B to U10 pin 4. Set TB=5 uS and control the data set-up time as shown below.

Check of SPI Address Select

Connect an oscilloscope channel A to U09 pin 2. Set TB=5uS and control the wave form as shown below. Control the same wave form on U09 pin 3,4,5,6,7,8 and 16.

Address Select U09 Pin2,3,4,5,-
6,7,8 and pin16.

3.6.5. PERFORMANCE CHECK OF MICROPROCESSOR MODULE 5 cont.

Connect an oscilloscope channel A to U09 pin 13. Set TB=500uS and control the wave form as shown below. Control the same wave form on U09 pin 14 and 15.

Address Select U09 Pin13, 14 and Pin15

CHECK OF SP-BUS TRANSMITTER/RECEIVER

Press the digits 0 and 1 at the same time. The equipment will now be in Quick Service mode and the display will show "SP- ".

Select the service programme SP-00-3 (ref. to chapter 3.10). If the SP-BUS does not work satisfactorily, an "E" will be displayed in the TX-display. Connect an oscilloscope to BNC connector J04 (SP-BUS output). Control that the wave form seen is approx. equal to the one shown below. The 8 data bit and parities bit will change every time the SP-BUS transmitter sends a new byte. Transmit speed is 4800 baud and the time between two bytes is approx. 14 mS.

Tx signal on SP-BUS.

CHECK OF EEPROM U05

In order to test the Electrical Erasable PROM, the service programme SP-10-0 has to be run. Press the digits 1 and 0 at same time. The equipment will now be in Quick Service mode and the display will show "SP- ". Then press the digit 1-0-0 and finish with ENT. The RX-display will read out "SP-10-0 and the TX-display will start to count from 0 to 512. If the counting stops with 512 and an "A" is shown, the EEPROM is ok. But if the counting is stopped between 0 and 512 and an "E" is shown, there must be a programming error.

3.6.8. MODULE PERFORMANCE CHECK OF POWER UNIT

3.6.8.1. Check of Voltage Regulators

1. Connect a voltmeter to the outputs of the voltage regulators and check the voltages according to the following table:

U01:	+15V	+1V
U02:	-15V	+1V
U03:	+15V	+1V
U04:	-15V	+1V
U06:	+5.3V	+0.2V
U07:	+3.5V	+0.3V

3.6.8.2. Check of RF Amplifier and Filter

1. Connect a 50 ohm resistor to the aerial socket J01-2. Two 100 ohm resistors in parallel soldered on a coax cable connected to the aerial socket are sufficient.
2. Connect an oscilloscope through a 10:1 probe to the 50 ohm resistor.
3. Connect a signal generator to P03-8 with an output power of -9 dBm.
4. Control of the lowpass filter response is carried out by changing the frequency of the signal generator and controlling the reading on the scope. Max. permissible ripple is 2 dB in the frequency range 1.6 MHz to 30 MHz.
5. Tune the signal generator to 22 MHz and read on the scope the voltage to $3.5 V_{pp} \pm 0.5V$.

3.7. ADJUSTMENT PROCEDURE

This chapter contains the adjustment procedure for all adjustable components in the RE2100.

3.7.1. ADJUSTMENT PROCEDURE FOR FRONT END AND RECEIVER UNIT

This chapter contains the following sections:

- 3.7.1.1. Adjustment of 70 MHz IF-Filter (Front End and Receiver)
- 3.7.1.2. Adjustment of 70 MHz Transformer (Receiver)
- 3.7.1.3. Adjustment of SSB/AM Filter (Receiver)
- 3.7.1.4. Adjustment of 2nd IF-Gain (Receiver)
- 3.7.1.5. Adjustment of Signal Meter (Receiver)
- 3.7.1.6. Adjustment of Earpiece Level (Receiver)

3.7.1.1. Adjustment of 70 MHz IF-Filter (Front End and Receiver)

The 70 MHz IF-filter is adjusted by tuning the three trimming coils L35-2, L36-2, L37-2, and the two transformers TR04-2, TR01-1.

The components L35-2, L36-2, L37-2 and TR04-2 are all located at the front end unit (module 2), while TR01-1 is located at the receiver unit (module 1).

The adjustment is performed by using the two service programmes SP-04-0 and SP-04-1. These programmes set-up the first local oscillator (L01) as a test signal and therefore no external signal generator is necessary.

1. Disconnect any input to the aerial socket.
2. Connect a voltmeter to test point TP1-1 for measuring the DC-output voltage from the AGC level detector.
3. Turn the RE2100 on.
4. Select service programme SP-04-0 as described in section 3.10.1. of this manual.
5. Tune the transformer TR01-1 (Receiver Module) and the trimming coil L37-2 (Front End Module) to maximum meter deflection.
6. Select service programme SP-04-1 (press <STOP> to terminate the first service programme).
7. Tune the transformer TR04-2 and the trimming coils L35-2 and L36-2 to maximum meter deflection.
8. Select service programme SP-04-0.
9. Turn off the AGC and adjust the manual RF GAIN until the DC-output voltage from the AGC level detector is about 5 volt.
10. Finetune all five components by repeating point 5-7. Remember to turn off the AGC in point 6 after selecting the service programme SP-04-1.

3.7.1. ADJUSTMENT PROCEDURE FOR FRONT END AND RECEIVER UNIT cont.:

NOTE! If the DC-output voltage from the AGC level detector is increased to a level above 9 Volt, it is necessary to readjust the manual RF-gain until the voltage level is about 5 Volt.

11. Press <TUNE> to leave the service programme mode.

3.7.1.2. Adjustment of 70 MHz Transformer (Receiver)

The position number of the 70 MHz transformer is TR01-1 and it is located at the receiver unit (module 1). The adjustment is performed by tuning TR01-1 until the DC-output voltage from the AGC level detector is maximum. The tuning is performed by using the service programme SP-04-0. This programme sets-up the first local oscillator (L01) as a test signal and therefore no external signal generator is necessary.

1. Execute points 1-4 in section 3.7.1.1.
2. Tune the 70 MHz transformer TR01-1 to maximum meter deflection.
3. Turn off the AGC and adjust the manual RF GAIN until the DC-output voltage from the AGC level detector is about 5 Volt.
4. Finetune TR01-1.
5. Press <TUNE> to leave the service programme mode.

3.7.1.3. Adjustment of SSB/AM-Filter (Receiver)

The SSB/AM-filter is adjusted by tuning the trimming capacitor C181 until the DC-output voltage from the AGC level detector is maximum. The trimming capacitor C18-1 is located at the receiver unit (module 1). The adjustment is performed by using the service programme SP-042. This programme sets-up the first local oscillator (L01) as a test signal and therefore no external signal generator is necessary.

1. Execute points 1-3 in section 3.7.1.1.
2. Select service programme SP-04-2.
3. Adjust the manual RF-gain until the DC-output voltage from the AGC level detector is about 5V.
4. Tune the trimming capacitor C18-1 to maximum meter deflection.
5. Press <TUNE> to leave the service programme mode.

3.7.1.4. Adjustment of 2nd IF-Gain (Receiver)

To meet the gain variations from one transistor to another, the 2nd IF-amplifier has been constructed with a reserve of power gain. This implies that the 2nd IF-gain may be very large, which may cause unstable conditions because of unwanted feedback.

It is therefore necessary to adjust the unregulated gain of the 2nd IF-amplifier, which must be done in accordance with the procedure given below.

The 2nd IF-gain is adjusted by trimming the resistor R203-1, which is located at the receiver unit (module 1).

The adjustment is performed by using a signal generator and an AC voltmeter.

3.7.1. ADJUSTMENT PROCEDURE FOR FRONT END AND RECEIVER UNIT cont.:

1. Connect the signal generator to the aerial socket at the front end unit.
2. Connect the AC voltmeter to earpiece output at testpoint TP2-1.
3. Turn the RE2100 on.
NOTE! The RE2100 must be on for at least five minutes before proceeding.
4. Select the setting of the signal generator and the RE2100 according to point 5.

5.

Signal Generator			RE2100	
Frequency	Level	Mode	Frequency	Mode
1991 kHz	33dB/uV	CW	1990 kHz	J3E

6. Measure the AC voltage at the earpiece output.
7. Change the generator output level to 0dB/uV.
8. Adjust the resistor R203-1 until the AC voltage at earpiece output is decreased by 4 dB relative to the level measured in point 6.

3.7.1.5. Adjustment of Signal Meter (Receiver)

The signal meter is adjusted by trimming the resistor R76-1, which is located at the receiver unit (module 1).

1. Disconnect any input to the aerial socket.
2. Turn the RE2100 on and make sure that J3E-mode (SSB) is selected and that the AGC is operative.
3. Adjust R76-1 until the first LED-bar in the display is just about to light.

3.7.1.6. Adjustment of Earpiece Level (Receiver)

The earpiece level is adjusted by trimming the resistor R52-1, which is located at the receiver unit (module 1).

The adjustment is performed by using the service programme SP-04-3. This programme sets-up the first local oscillator (LO1) as a test signal and therefore no external signal generator is necessary.

1. Disconnect any input to the aerial socket.
2. Connect a voltmeter to earpiece output at testpoint TP2-1 for measuring the AC-voltage.
3. Turn the RE2100 on.
4. Select service programme SP-04-3.
5. Adjust R52-1 until the earpiece level is $0.8 V_{RMS} \pm 0.1 V_{RMS}$.
6. Press <TUNE> to leave the service programme mode.

3.7.2. ADJUSTMENT PROCEDURE FOR SYNTHESIZER UNIT

This chapter contains the following sections:

- 3.7.2.1. Adjustment of TCXO
- 3.7.2.2. Adjustment of API Voltage in PLL1
- 3.7.2.3. Adjustment of the VCO Circuits in PLL1
- 3.7.2.4. Adjustment of the VCO Circuits in PLL2

3.7.2.1. Adjustment of TCXO

The Temperature Compensated X-tal Oscillator (TCXO) delivers the reference frequency, which is common for both PLL1 and PLL2.

The adjustment is performed by measuring the TCXO frequency at the output of the TCXO buffer at testpoint TP4-3 (collector of transistor Q26-3).

1. Turn the RE2100 on.
NOTE! The RE2100 must be on for at least 15 minutes before the adjustment is carried out.
2. Connect the counter to TP4-3 through passive probe.
3. Adjust the TCXO, until the frequency at TP4-3 is 10.731520 MHz $\pm$ 1 Hz.

3.7.2.2. Adjustment of API Voltage in PLL1

The API voltage is adjusted by trimming the resistor R88-3, which is located at the Synthesizer Unit (module 3).

The adjustment is performed by using the service programme SP-04-4. This programme sets up a special receiver mode, where the API sideband from the L01 is passed through the SSB crystal filter and the 2nd IF-amplifier. The level of the API sideband can then be measured as a DC voltage at the level detector output at testpoint TP1-1.

1. Turn the RE2100 on.
2. Connect the DC voltmeter to TP1-1 located on the Receiver Unit (module 1).
3. Select service programme SP-04-4 as described in this manual, section 3.10.1.
4. Adjust potentiometer R88-3 for minimum meter deflection.

3.7.2.3. Adjustment of the VCO Circuits in PLL1

The PLL1 consists of four independent Voltage Controlled Oscillators, which each covers about a quarter of the whole frequency band of 30 MHz.

The VCO circuits are adjusted by four individual coils. The adjustment is performed at the upper frequency in each of the four VCO bands and the coils are adjusted until the output voltage from the active loop filter is -11.0 Volt.

1. Turn the RE2100 on.
2. Connect the voltmeter to TP1-3.

3.7.2. ADJUSTMENT PROCEDURE FOR SYNTHESIZER UNIT cont.:

3. Key-in the RX-frequencies and adjust VCO coils according to table 4 until voltage on TP1-3 is -11.0 Volt.

4.

RX-frequency	Adjustment of
7499.0	TR03
14999.0	TR04
22499.0	TR05
29999.0	TR06

5. Key-in the RX-frequencies according to table 6 and check the voltage on TP1-3 to be -3 Volt + 1.0 Volt.

NOTE! No adjustments of VCO coils shall be made.

6. RX-frequency

100.0

7500.0

15000.0

22500.0

3.7.2.4. Adjustment of the VCO Circuits in PLL2

The PLL2 consists of two independent Voltage Controlled Oscillators, which are used in USB and LSB mode respectively.

The VCO circuits are adjusted by two individual coils, which are adjusted until the output voltage from the active loop filter is -6.5 Volt.

1. Turn the RE2100 on.
2. Connect the voltmeter to TP5-3.
3. Select J3E mode and adjust TR08 until the voltage on TP5-3 is -6.5 Volt.
4. Select LSB mode and adjust TR07 until the voltage on TP5-3 is -6.5 Volt.

3.7.3. ADJUSTMENT PROCEDURE FOR EXCITER UNIT

This chapter contains the following sections:

- 3.7.3.1. Adjustment of Compressor and AF Limiter
- 3.7.3.2. Adjustment of Carrier Limit Amplifier
- 3.7.3.3. Adjustment of Modulator
- 3.7.3.4. Adjustment of RF Limiter
- 3.7.3.5. Adjustment of Carrier Insertion
- 3.7.3.6. Adjustment of Step Attenuator
- 3.7.3.7. Adjustment of 70 MHz IF

For best stability, all coils and transformers are adjusted with the cores in the lower resonant position.

For each circuit to be adjusted, it is a condition that all the previous circuits are adjusted to obtain the best possible adjustment.

In the adjustment procedure for the Exciter Unit, four service programmes are used, SP-05-0, 1, 2, and 3. How to select the service programmes is described in section 3.10.1.

3.7.3.1. Adjustment of Compressor and AF Limiter

The compression level is adjusted by R35-4 and the cutting symmetry is determined by R57-4.

1. Connect the scope probe to the emitter of Q04-4 (TP1-4).
2. Select service programme SP-05-0.
3. A combined square wave signal (tune tones) is seen on the scope.
4. Turn R35-4 clockwise until the signal reaches a limiting level.
5. Adjust R57-4 to obtain a symmetrical cutting of the signal. That is, when both top and bottom of the signal reach the limiting level simultaneously when the signal is increased by means of R35-4.
6. Turn R35-4 fully clockwise.
7. Adjust the scope until there is full deflection (8 div.) on the scope.
8. Adjust R35-4 until the deflection seen on the scope is 7 div. peak-peak. The signal is now under the limiting level.
9. If this adjustment is the only one executed after repair, please execute 3.7.3.4. Adjustment of RF Limiter.

3.7.3.2. Adjustment of Carrier Limit Amplifier

1. Connect scope probe to the connection between R93-4 and C75-4 (TP2-4).
2. Select service programme SP-05-0.
3. Press handset key.

3.7.3. ADJUSTMENT PROCEDURE FOR EXCITER UNIT cont.:

4. Adjust L05-4 to maximum signal.
5. Release handset key.

3.7.3.3. Adjustment of Modulator

1. Connect scope probe to the connection between C66-4 and C67-4 (TP3-4).
2. Select service programme SP-05-0.
3. Press handset key.
4. Adjust TR01-4 to maximum signal.
5. Release handset key.
6. Select service programme SP-05-1.
7. Select H3E on the keyboard.
8. Press handset key.
9. Adjust R190-4 to minimum signal (noise) on the scope.
10. Release handset key.
11. If this adjustment is the only one executed after repair, please execute 3.7.3.4. Adjustment of RF Limiter.

3.7.3.4. Adjustment of RF Limiter

1. Connect scope probe to emitter of Q19-4 (TP4-4).
2. Select service programme SP-05-0.
3. Press handset key.
4. Adjust L07-4, L08-4, and TR02-4 to maximum signal.
5. Turn R87-4 fully clockwise. The signal is cut.
6. Adjust scope until there is full deflection on the scope (8 div.).
7. Adjust R87-4 until the deflection seen on the scope is 7.2 div. The signal is not cut.
8. Release handset key.

3.7.3.5. Adjustment of Carrier Insertion

1. Connect scope probe to emitter of Q19-4 (TP4-4).
2. Select service programme SP-05-0.
3. Press handset key.

3.7.3. ADJUSTMENT PROCEDURE FOR EXCITER UNIT cont.:

4. Adjust scope until there is full deflection (8 div.) on the screen.
5. Release handset key and press <ENT> on the keyboard.
6. Select service programme SP-05-1.
7. Select H3E mode on the keyboard.
8. Press handset key.
9. Adjust R92-4 until the deflection on the screen of the carrier signal is 4.4 div.
10. Release handset key.

3.7.3.6. Adjustment of Step Attenuator

1. Connect scope probe to emitter of Q18-4 (TP5-4).
2. Select service programme SP-05-0.
3. Press handset key.
4. Adjust L09-4 to maximum signal.
5. Release handset key and press <ENT> on the keyboard.
6. Select service programme SP-05-2.
7. Connect another scope probe to R143-4 (TP6-4). This signal is used to trig the scope. The scope must be triggered by the negative transition.
8. On the scope is now seen a staircase waveform. When adjusting R159-4 it can be seen that one of the steps changes amplitude.

3.7.3. ADJUSTMENT PROCEDURE FOR EXCITER UNIT cont.:

9. Adjust R159-4 until the step, which changes amplitude, is approximately equal to the neighbour steps.
10. Press <ENT> on the keyboard.
11. To adjust the RF output power level from the Exciter Unit to the Power Unit (8), it is a condition that both the 70 MHz IF filter and the Power Unit are correctly adjusted. If not, perform section 3.7.3.7. and 3.7.4.2.
12. Connect a 50 ohm resistor to the aerial socket. Two 100 ohm resistors in parallel soldered on a coax cable connected to the aerial socket are sufficient.
13. Connect an oscilloscope through a 10:1 probe to the 50 ohm resistor.
14. Select service programme SP-05-0.
15. Press handset key.
16. Adjust R120-4 until the signal on the scope is 3.5 Vpp. If a milliwattmeter is connected to the aerial socket J01-2 it should read 12 dBm in 50 ohm.
17. Release handset key.

3.7.3.7. Adjustment of 70 MHz IF

When using the two service programmes SP-05-1 and SP-05-3, the 70 MHz IF filter can be adjusted.

1. Connect scope probe to the output of the Power Unit at P04-8 (TP1-8).
2. Select service programme SP-05-3.
3. Select H3E on keyboard and press handset key.
4. Adjust L10-6, L11-4 and L12-4 several times to obtain maximum signal on the scope.
5. Release handset key and press <ENT> on the keyboard.
6. Select service programme SP-05-1.
7. Select H3E mode on keyboard and press handset key.
8. Readjust only L10-4 to maximum signal.
9. Release handset key.

3.7.4. ADJUSTMENT PROCEDURE FOR POWER UNIT.

This chapter contains the adjustments for the 5V regulator and the RF power output level to the transmitter.

3.7.4.1. Adjustment of +5V

The +5V output voltage must have a value between 5.1V and 5.5V to ensure stability in the Synthesizer Unit. Normally the resistor R33-8 is removed at the factory. If the regulator U06-8 has been changed for repair then check the output voltage.

Connect a voltmeter to R16-8 (TP2-8) and measure the output voltage with R33-8 removed, and one of the following three situations occur:

	Measured Value		Adjusted Value
a:	$V_o < 5.15V$	=> R32-8 removes	=> $5.10 < V_o < 5.30V$
b:	$5.15V < V_o < 5.40V$	=> nothing	=> $5.15V < V_o < 5.40V$
c:	$V_o > 5.40V$	=> R33-8 replaces	=> $5.25 < V_o < 5.45V$

3.7.4.2. Adjustment of RF Output Level

1. Connect a 50 ohm resistor to the aerial socket J01-2. Two 100 ohm resistors in parallel soldered on a coax cable connected to the aerial socket are sufficient.
2. Connect an oscilloscope through a 10:1 probe to the 50 ohm resistor.
3. Connect a signal generator to P03-8. Tune the signal generator to deliver -9 dBm output power at 22 MHz.
5. Select service programme SP-05-0 to start-up the voltage regulators U01-8 and U02-8.
6. Adjust R30-8 until the output voltage seen on the scope is 3.25 Vpp.
7. If a milliwattmeter is connected to the aerial socket J01-2 it should read 14 dBm. RF gain at 22 MHz is 23 dB.

3.8. NECESSARY ADJUSTMENT AND CHECK AFTER REPAIR

GENERAL

After repair of the RE2100 it may be necessary to do some adjustments and checks.

The extent of these adjustments and checks can only be decided by the person, who has done the repair, and this manual section must only be looked upon as a guide.

Any repair must, as mentioned previously, be followed by a function check after reinstallation of the RE2100.

RECEIVER UNIT (MODULE 1)

After a Change of the Module

Execute 3.7.1.5. Adjustment of Signal Meter, and 3.5.2. Performance Check of Receiver.

Repair in 2nd Mixer and the Corresponding Input Matching Circuit

Execute 3.7.1.2. Adjustment of 70 MHz Transformer, and 3.5.2.1. Performance Check of Receiver Sensitivity.

Repair in L02 Buffer

Execute 3.6.1.2. Check of L02 and Reinjection Signals, and 3.5.2.1. Performance Check of Receiver Sensitivity.

Repair in SSB/AM Crystal Filters and the Corresponding Input/Output Matching Network

Execute 3.7.1.3. Adjustment of SSB/AM Filter.

Execute 3.6.1.3. Check of Crystal Filters, and 3.5.2.1. Performance Check of Receiver Sensitivity.

Repair in 2nd IF Amplifier and AGC Circuit

Execute 3.7.1.4. Adjustment of 2nd IF Gain, and 3.7.1.5. Adjustment of Signal Meter.

Execute 3.5.2.5. Performance Check of Receiver AGC, and 3.5.2.1. Performance Check of Receiver Sensitivity.

Repair in Detector

Execute 3.5.2.1. Performance Check of Receiver Sensitivity, and 3.5.2.2. Performance Check of Receiver Distortion.

Repair in Audio Frequency Filter

Execute 3.5.2.3. Performance Check of Receiver Audio Passband, and 3.5.2.1. Performance Check of Receiver Distortion.

Repair in Earpiece Amplifier

Execute 3.7.1.6. Performance Check of Earpiece Level, and 3.5.2.2. Performance Check of Receiver Distortion.

Repair in Squelch Circuit

Execute 3.5.2.6. Performance Check of Receiver Squelch.

3.8. NECESSARY ADJUSTMENT AND CHECK AFTER REPAIR cont.:

FRONT END UNIT (MODULE 2)

After a Change of the Module

Execute 3.5.2.1. Performance Check of Receiver Sensitivity, and 3.5.2.3. Performance Check of Receiver Audio Passband.

Repair in Input Protection Circuit and Pre-Filters

Execute 3.5.2.1. Performance Check of Receiver Sensitivity, and 3.5.2.2. Performance Check of Receiver Distortion.

Repair in 1st Mixer and 70 MHz IF Filter

Execute 3.7.1.1. Adjustment of 70 MHz IF Filter.

Execute 3.5.2.1. Performance Check of Receiver Sensitivity, and 3.5.2.3. Performance Check of Receiver Audio Passband.

Repair in L01 Buffer

Execute 3.5.2.1. Performance Check of Receiver Sensitivity.

SYNTHESIZER UNIT (MODULE 3)

After a Change of the Module

Execute 3.5.2.1. Performance Check of Receiver Sensitivity, and 3.5.2.4. Performance Check of Receiver Clarifier and Frequency.

Execute 3.5.3.2. Performance Check of Exciter Frequencies and Classes of Emission.

Repair in the TCXO and Buffer

Execute 3.7.2.1. Adjustment of TCXO.

Repair in Phase Detector, Current Mirror and API Circuit (PLL1)

Execute 3.7.2.2. Adjustment of API Voltage in PLL1, and 3.7.2.3. Adjustment of the VCO Circuits in PLL1.

Execute 3.5.2.1. Performance Check of Receiver Sensitivity, and 3.5.2.4. Performance Check of Receiver Clarifier and Frequency.

Repair in the PLL1

Execute 3.7.2.3. Adjustment of the VCO Circuit in PLL1.

Execute 3.5.2.1. Performance Check of Receiver Sensitivity, 3.5.2.4. Performance Check of Receiver Clarifier and Frequency, and 3.5.3.2. Performance Check of Exciter Frequencies and Classes of Emission.

Repair in the PLL2

Execute 3.7.2.4. Adjustment of the VCO Circuits in PLL2.

Execute 3.5.2.1. Performance Check of Receiver Sensitivity, 3.5.2.4. Performance Check of Receiver Clarifier and Frequency, and 3.5.3.2. Performance Check of Exciter Frequencies and Classes of Emission.

EXCITER UNIT (MODULE 4)

After a Change of the Module

Execute 3.5.3. PERFORMANCE CHECK OF EXCITER.

Repair in AF Selector, Compressor, and AF Limiter

Execute 3.7.3.1. Adjustment of Compressor and AF Limiter.

Execute 3.6.4.5. Check of RF Limiter and Carrier Insertion.

3.8. NECESSARY ADJUSTMENT AND CHECK AFTER REPAIR cont.:

Repair in Carrier Limiter Amplifier

Execute 3.7.3.2. Adjustment of Carrier Limiter Amplifier, and 3.7.3.4. Adjustment of RF Limiter, and 3.7.3.5. Adjustment of Carrier Insertion.

Repair in Modulator and Modulation Level Amplifier

Execute 3.7.3.3. Adjustment of Modulator, and 3.7.3.4. Adjustment of RF Limiter.

Execute 3.6.4.5. Check of RF Limiter and Carrier Insertion.

Repair in RF Limiter, Carrier Insertion and SSB Filter

Execute 3.7.3.4. Adjustment of RF Limiter, and 3.7.3.5. Adjustment of Carrier Insertion.

Repair in Step Attenuator

Execute 3.7.3.6. Adjustment of Step Attenuator.

Repair in 70 MHz IF

Execute 3.7.3.6. Adjustmnet of 70 MHz IF, and 3.7.3.6. Adjustment of Step Attenuator, section 3.7.3.6. points 12. - 17.

PROCESSOR UNIT (MODULE 5)

After a Change or Repair of the Module

Execute 3.5.1.1. and 3.5.1.2. Performance Check of Display and Keyboard.

Execute 3.5.2.4. Performance Check of Receiver Clarifier and Frequency, and 3.5.3.2. Performance Check of Exciter Frequencies and Classes of Emission.

KEYBOARD UNIT (MODULE 6)

After a Change or Repair of the Module

Execute 3.5.1.2. Performance Check of Keyboard.

DISPLAY UNIT (MODULE 7)

After a Change or Repair of the Module

Execute 3.5.1.1. Performance Check of Display.

POWER UNIT (MODULE 8)

After a Change of the Module

Execute 3.5.3. PERFORMANCE CHECK OF EXCITER.

Repair of +5V Regulator

Execute 3.7.4.1. Adjustment of +5V.

Repair of the Other Voltage Regulators

Execute 3.6.8.1. Check of Voltage Regulators.

Repair in RF Amplifier and Filter

Execute 3.7.4.2. Adjustment of RF Output Level, and 3.6.8.2. Check of RF Amplifier and Filter.

3.9. FUNCTION CHECK

The function check is a simple test to ensure that the RE2100 is working properly after installation.

The function check must always be carried out after a repair of the RE2100. Any repair of the RE2100 must be followed by a performance check, and after reinstallation a function check must be carried out in order to make sure that the fault has been repaired and that the RE2100 is working correctly together with the installed transmitter T2130 and aerial coupler AT2110.

1. Turn on the VOL-OFF switch and control that noise is heard in the loudspeaker and the display is alight.
2. Press the keyboard buttons 0 and 1 simultaneously.
3. Select the test programme SP-00-2.
4. Control that all the leds in the display are activated, the mode indicating light emitting diodes are toggled, and the three light emitting diodes, indicating the power level, are alight.
5. Press the RF-GAIN control fully counter clockwise and control that all the light emitting diodes in the signal meter are alight.
7. Key-in a known broadcast station in the frequency range 100 - 384 kHz.
8. Notice that the detected AF signal is heard from the loudspeaker and from the handset earpiece without distortion.
9. Toggle the keyboard button MODE, until J3E mode is chosen.
10. Notice that no beat note is heard in the loudspeaker.
11. Press the keyboard FREQ arrow buttons to toggle the 100 Hz decimal up and down.
12. Control that the beat note heard in the loudspeaker changes with the 100 Hz steps.
13. Key-in a known broadcast station in the frequency range 385 - 1600 kHz.
14. Notice that the detected AF signal is heard from the loudspeaker without distortion.
15. Key-in a known coastal station frequency in the frequency range 1600 - 3990 kHz.
16. When listening to the coastal station, activate the clarifier and control that it is working properly.
17. Key-in one ITU channel in each of the maritime bands from 4.0 - 25.0 MHz and control that the receiver is working properly.

3.9. FUNCTION CHECK cont.:

18. Activate a scan programme or key-in a scan programme, and control that the scan function is working correctly.
19. Active the keyboard AGC and SQ button and control that the leds marked AGC and SQ can be toggled.
20. When activating the SQ function, control that the noise from the loudspeaker disappears.
21. Select the lowest transmitting frequency and press first TX, and then TUNE. When the tune lamp extinguishes, press the handset key and whistle into the microphone. While whisteling, release the handset key.
22. Press the keyboard buttons 0 and 1 simultaneously.
23. Select the test programme SP-20-0.
24. Press the keyboard button ENT.
25. The TX display will now show the battery voltage when transmitting. This voltage must be above 22V DC.
26. Select the test programme SP-22-2.
27. Press the keyboard button ENT.
28. The TX display shows the latest measured V_{forward} . This voltage must be above 9V DC.
29. Select the test programme SP-23-0.
30. Press the keyboard button ENT.
31. The TX display shows the SWR, which must be below 2.
32. Select the test programme SP-26-1.
33. Press the keyboard button ENT.
34. The TX display shows the drive setting, which must be above 12.
35. Press the keyboard button TUNE.
36. Check that it is possible to tune and to transmit in all maritime bands.
37. Press the keyboard button TX, and then the button DUMMY LOAD.
38. Activate the handset key.
39. When the tune lamp extinguishes, press the keyboard buttons SEND ALARM and TEST ALARM simultaneously.
40. The transmitter sends the alarm tone signal to the dummy load, which can be seen on the AE-current meter.
41. The alarm tones will be heard in the handset earpiece.
42. Press the keyboard button ENT.
43. The transmitter stops transmitting.
44. As a final test, make a call to a coast station.

3.10. SELECTION AND DESCRIPTION OF THE SERVICE PROGRAMMES

3.10.1. How to Select a Service Programme

In order to help the operator, and the service engineer during installation or repair, the RE2100 has some built-in service programmes.

The RE2100 has a service mode, which is activated by pressing the keyboard buttons 1 and 0 simultaneously. The display of the RE2100 will now show 'SP-'.

The various service programmes can now be selected by keying-in a three digit number. The display of the RE2100 will then show 'SP-XX-X'.

A new service programme may be chosen after the keyboard button ENT has been pressed once. The display shows 'SP-' again, and a new three digit number can be keyed-in.

In order to return to normal operation mode, press the keyboard button TUNE/CLARIF.

3.10.2. Description of Service Programmes

SP-00-X TEST OF PROCESSOR, KEYBOARD AND DISPLAY MODULE

When 00 has been keyed-in, the RX display shows 'SP-00-', and the programmes 0 to 3 and 8 may be selected.

SP-00-0 READ OUT OF SOFTWARE VERSION NUMBER

In the TX display a 4 digit number will be read out, possibly followed by a letter. The number indicates S. P. Radio's internal software number and the letter indicates the software release.

Ex. 1085E => C-number C1085 and rel. E.

SP-00-1 READS OUT WHICH ITU FREQUENCY TABLE IS USED

When P-91 is read out, an earlier ITU table is used. When A-91 is read out, the ITU table in force from 1st June 1991 is used.

When keying-in the digit 0 or 1, the read out will be changed from A-91 to P-91 or P-91 to A-91 respectively.

SP-00-2 STARTS TEST OF THE DISPLAY

This test programme is used in the performance check, section 3.5.1.1.

When pressing <ENT> during the test, the test procedure stops. When pressing <ENT> again, the programme steps forward. When pressing <0>, the programme continues again automatically.

SP-00-3 TEST OF SP-BUS

This test programme is used in the performance check, section 3.5.1.1.

The processor sends a byte to itself via the serial SCI communication port. Each time an error is received, the display reads-out an 'E'. If there is no error, a bar '-' runs through the TX display.

3.10. SELECTION AND DESCRIPTION OF THE SERVICE PROGRAMMES cont.:

SP-00-8 TEST OF KEYBOARD

This test programme is used to test all the keyboard buttons. When the programme is selected, press the keyboard from the top of the right corner down to the left corner. E.g. 1,2,3,4,5,6,-FREQ DOWN,.....0,,ENT. When the buttons are pressed, the display reads-out the number of the button (ref. chapter 5.6. KEYBOARD UNIT). If the button does not work, the display reads-out the number of the button with a letter "E", when the next button is pressed.

SP-04-X TEST OF FRONTEND, RECEIVER AND SYNTHESIZER MODULE

When 04 has been keyed in, the RX display shows 'SP-04-', and the programmes 0 to 7 may be selected.

SP-04-0 ADJUSTMENT OF 70 MHz RECEIVER FILTER

This test programme is used in the adjustment procedure, sections 3.7.1.1. and 3.7.1.2, where it sets up the synthesizer, frontend, and receiver module for adjustment of the 70 MHz intermediate filter.

SP-04-1 ADJUSTMENT OF 70 MHz RECEIVER FILTER

This test programme is used in the adjustment procedure, section 3.7.1.1., where it sets up the synthesizer, frontend, and receiver module for adjustment of the 70 MHz intermediate filter.

SP-04-2 ADJUSTMENT OF SSB/AM RECEIVER FILTER

This test programme is used in the adjustment procedure, section 3.7.1.3., where it sets up the synthesizer, frontend, and receiver module for adjustment of the 10.7 MHz SSB/AM intermediate filter.

SP-04-3 ADJUSTMENT OF EARPIECE LEVEL

This test programme is used in the adjustment procedure, section 3.7.1.6., where it sets up the synthesizer, frontend, and receiver module for adjustment of the earpiece level.

SP-04-4 ADJUSTMENT OF API VOLTAGE

This test programme is used in the adjustment procedure, section 3.7.2.2., where it sets up the synthesizer, frontend, and receiver module for adjustment of the API sideband level.

SP-04-5 TEST OF LO1 AND LO2 SIGNALS TO EXCITER

This test programme is used in the module performance check, section 3.6.1.5., where it sets up the synthesizer, exciter, and frontend module, in order to control that the local oscillator signals are present at the exciter module.

3.10. SELECTION AND DESCRIPTION OF THE SERVICE PROGRAMMES cont.:

SP-04-6 TEST OF ATTACK AND DECAY TIME FOR AGC IN SSB MODE

This test programme is used in the module performance check, section 3.6.1.5., and performance check, section 3.5.2.5., where it sets up the synthesizer, frontend, and receiver module, in order to control that the SSB AGC attack and decay times are inside the limits.

SP-04-7 TEST OF ATTACK AND DECAY TIME FOR AGC IN AM MODE

This test programme is used in the module performance check, section 3.6.1.5., and performance check, section 3.5.2.5., where it sets up the synthesizer, frontend, and receiver module, in order to control that the AM AGC attack and decay time are inside the limits.

SP-05-X TEST OF EXCITER AND POWER MODULE

When the RE2100 is not connected with a transmitter T2130, it is not possible to activate the exciter module. It is therefore necessary to activate a test programme to get the exciter to work.

When 05 has been keyed-in, the RX display shows 'SP-05-', and the test programmes 0 to 6 may be selected.

SP-05-0 EXCITER ACTIVATED IN TUNE MODE

The exciter output frequency is set to $f_{TX} = 22000.0$ kHz, the tune tones can be activated by the handset key, and the transmit mode is J3E. Exciter step attenuator is set to max. output power.

SP-05-1 EXCITER ACTIVATED IN TELEPHONY MODE

The exciter output frequency is set to $f_{TX} = 22000.0$ kHz, LF signal generator can be connected to testbox terminal AF to Telex, and the handset key is valid. Mode shift is possible, but the modulation is turned off in H3E mode. Exciter step attenuator is set to max. output power.

SP-05-2 TEST OF EXCITER STEP ATTENUATOR

The exciter output frequency is set to $f_{TX} = 22000.0$ kHz, and the step attenuator is incremented with 1 step every 700 μ S, until step 63 is reached. Then the attenuator is reset to step 0.

The test programme is used in the performance check, section 3.5.3.4., module performance check, section 3.6.4.6., and module adjustment, section 3.7.3.6.

SP-05-3 TEST OF EXCITER 70 MHz FILTER

This test programme is used in the module performance check, section 3.6.4.7., and in module adjustment, section 3.7.3.7., where it sets up the synthesizer and exciter to control the 70 MHz intermediate filter.

SP-05-4 EXCITER ACTIVATED IN TELEPHONY MODE

The exciter is activated as in test programme SP-05-1, but the exciter output frequency is changed to 28000.0 kHz.

3.10. SELECTION AND DESCRIPTION OF THE SERVICE PROGRAMMES cont.:

SP-05-5 EXCITER ACTIVATED IN TELEPHONY MODE

The exciter is activated as in test programme SP-05-1, but the exciter output frequency is changed to 14900.0 kHz.

SP-05-6 EXCITER ACTIVATED IN TELEPHONY MODE

The exciter is activated as in test programme SP-05-1, but the exciter output frequency is changed to 1600.0 kHz and modulation is possible in H3E mode

5. CIRCUIT DESCRIPTION AND SCHEMATIC DIAGRAMS

5.1. RECEIVER UNIT (MODULE 1)

The receiver unit consists of a 70.0 MHz to 10.7 MHz mixer followed by an SSB/AM filter and a gain regulated IF amplifier. From the amplifier the signal is fed to the detector and low frequency filter unit. The receiver unit contains low frequency derived squelchs which can be set to control the low frequency output.

SECOND MIXER AND CRYSTAL FILTERS

The signal from the 70 MHz selectivity (module 2) is led through the balanced transformer TR01 to the gates of the J-FET's Q01 and Q02.

The second LO signal from the frequency synthesizer (module 3) is led through the LO-buffer Q03 and BPF (L01, L03, L04, and C04, C05, C11) in order to give about +17 dBm signal to the sources of the FET's. The mixed signals are fed through the balanced transformer TR02 and the impedance matching network (C17-C19 and R10) to one of the two high order monolithic crystal filters FL01 or FL02. The filter selection is controlled by the microprocessor through the shift register U10, pin 2..

IF AMPLIFIER

The signal from the crystal filters is fed through the diode D07 or D08 to the IF amplifier.

The IF amplifier consists of transistors Q07-Q11 and filter FL03 in cascade.

The gain in Q07, Q08, and Q09, which are dual gate Mos-FET's, is controlled by the AGC voltage applied to gate 2 of the FET's. This is done to keep the input level to the detector at the same level, independent of the input level to the receiver. From Q09 the signal is led to an amplifier built-up around Q10 and further to the ceramic filter FL03, which reduces the noise bandwidth to about 300 kHz. From the ceramic filter, the signal is fed through the emitter follower Q11 to the detector.

AGC GENERATOR

From the amplifier Q11 the signal is fed to the common emitter amplifier Q16. The voltage gain in this amplifier determines through the AGC system the magnitude of the output from the IF amplifier.

From the amplifier Q16 the signal is fed to transistor Q14, which together with R89, R91, C72, and C71 forms a magnitude detector.

SSB Mode

In SSB mode the signal from the magnitude detector ensures fast control of the gain in the IF amplifier. A slow control of the gain in the IF amplifier is activated by feeding the detector output voltage to the amplifier U03/2. U03/2 buffers the charging of C69 through D11 and R64 and the charging is removed from C69 through R63.

5.1. RECEIVER UNIT (MODULE 1) cont.:

The voltage on C69 is fed through the unity gain buffer U03/1 and D10 to the cathode of D14, where it is added to the actual voltage level from the detector. The added voltage is then subtracted from a reference voltage in U03/3 to make the AGC voltage, which is fed through an LP filter to the gates of Q07, Q08, and Q09.

The fast AGC system ensures noise immunity and the slow AGC system will decrease distortion caused by the AGC on an SSB signal.

AM Mode

In AM mode C71 is connected parallel to C72 through Q15. This increases both rise and fall time for the (fast) AGC system, so that modulation compression does not occur. The slow SSB-AGC is disabled by shunting C69 through Q04.

The manual IF gain voltage is added to the AGC system through D13. In scan mode the IF gain is set to max., independent of the position of the IF gain potentiometer (on module 7), by short-circuiting the potentiometer with Q12.

To switch the AGC system off, C71 (and C72 in AM mode) is short-circuited with Q13.

All mode shifts in the AGC system are controlled by the microprocessor through the shift register U10.

DETECTOR

The detector circuit, which can demodulate A3E, H3E, R3E, and J3E is built-up around U05. Switching between the two different detector modes, AM and SSB mode is controlled by the microprocessor through U10, Q17 and the diode switching circuit built-up around D17-D20. AM: D18 and D20 ON, SSB: D17 and D19 ON.

AM Mode

In AM mode the principle is to remove the modulation from the IF signal through the limiting amplifier (pin 1) and leave just the carrier signal. This signal is then mixed with the original IF signal (pin 9) to create the wanted AF signal (pin 6).

5.1. RECEIVER UNIT (MODULE 1) cont.:

SSB Mode

In SSB mode the carrier reinjection signal (pin 1) is simply mixed with the IF signal (pin 9) and the AF signal is then created.

U05 features a muting facility controlled by the microprocessor by applying voltage to pin 5.

AF FILTERS

To reduce white noise from the non-tuned IF amplifier, the AF signal from the detector is led through three active filters in cascade.

A 5th order, 3 kHz lowpass filter is built-up around U04/3 and U04/4. A 3rd order, 70 Hz highpass filter is built-up around U04/1, and a 3rd order, 350 Hz highpass filter is built-up around U04/2.

AM Mode

In AM mode only the LP filter and the 70 Hz HP filter is used. This is done by applying a logic high voltage to the analog switch U07, pin 9.

SSB Mode

In SSB mode all filters are used by applying a logic low voltage to the analog switch U07, pin 9.

Filter selection is controlled by the microprocessor through the shift register U10, pin 2.

5.1. RECEIVER UNIT (MODULE 1) cont.:

AF SWITCHES

From the output of the AF filter, the signal is fed through a number of analog switches, which are all included in the three IC's U7, U8, and U9. These switches are used to control the transfer of AF signals between the RE2100 and the peripheral equipment, which as an example could be a telex modem, a duplex receiver, and one or more remote control units. The interconnection between the individual switches is shown in the block diagram below.

Block Diagram AF Switches

AF OUTPUT AMPLIFIERS

From the AF switches, the signals are led to three different output amplifiers, which are described below.

AF Pre. Amplifier (Loudspeaker Output)

The purpose of the Pre. Amplifier is to buffer the AF signal before it is led to the power amplifier placed on module 4 in T2130. The output level can either be controlled by the volume potentiometer or by a constant voltage divider. The constant voltage divider is used in the situation where an intercom call to the RE2100 is detected. This situation is indicated by a ringing tone in the loudspeaker and to avoid this tone from vanishing it must necessarily be kept independent of the volume potentiometer.

5.1. RECEIVER UNIT (MODULE 1) cont.:

Earpiece Amplifier

The input signal to the earpiece amplifier is fed through the adjustable resistor R52, where the output level can be selected. The earpiece output can be means of P1 be selected to follow the squelch or not.

0 dBm Amplifier

In this amplifier the AF signal is amplified in order to give a 0 dBm output (in 600 ohm). The 0 dBm signal is led to the remote control units and it can by means of P4 be selected to follow the squelch or not.

SQUELCH

The squelch is voice activated, which is realized by detecting whether there is a change in the mean frequency at the AF-filter output. The squelch circuit, which contains limiting amplifier, frequency to voltage converter, voltage change detector, and hold circuit, generates a signal by which the microprocessor controls the squelch switch U07 at the receiver output.

Limiting Amplifier

U02/2 and U02/1 are connected as amplifier with about 100 dB voltage gain so that the output from U02/1 will be square wave with the same frequency as the input signal from the AF filter.

Frequency to Voltage Converter

The signal from the limiting amplifier is fed to the frequency to voltage converter, built-up around C99-C100, D26-D27, R142, and U02/4. The output from the converter is a voltage with an amplitude depending on the input frequency.

Voltage Change Detector

The voltage from the frequency to voltage converter is fed to capacitor C98 which only will pass a variation in the DC voltage. The resulting signal is amplified and filtered in the circuit built around U02/3. The inverter U01/3 and D22-D23 provide both positive and negative changes in the voltage to be converted to a positive change before the signal reaches the hold circuit.

Hold Circuit

The hold circuit has two functions. Fast opening for the AF signal when a conversation begins and keeping it open for a period after the conversation stops, e.g. during a short interruption of the conversation.

The signal from the voltage change detector is fed to comparator U01/4, which goes high and buffers the charging of C95 through D21 and R120 when the input signal is higher than the reference voltage (determined by R127-R128). The charging is removed from C95 through R119. As long as the voltage on C95 is higher than the reference voltage determined by R117-R118 the output from the comparator U01/1 will be high.

5.1. RECEIVER UNIT (MODULE 1) cont.:

Microprocessor Controlling

The output from the comparator U01/1 is led to the microprocessor. If the microprocessor detects a high voltage, it will turn the squelch switch ON and the AF-signal will then reach the loudspeaker, the earpiece and the 0 dBm amplifier.

When a conversation stops, C95 will slowly be discharged through R119. After about seven seconds the voltage across C95 will fall below the reference voltage and the output of comparator U01/1 will go low. This will be detected by the microprocessor, which will turn the squelch OFF.

In scan mode the squelch circuit is used to control scanning by detecting whether the receiver is scanning a channel with voice activity.

If the microprocessor detects a high voltage at the output of the comparator U01/1, it will immediately reset it by discharging C95 through Q20.

If the receiver actually receives a voice signal it will quickly build-up a new voltage across C95 and the output of the comparator will go high again. This cycle of measuring the comparator voltage and resetting it will be repeated six times to prevent noise spikes from stopping the scanning.

If the microprocessor after these six dischargings still detects a high voltage, it will stop the scanning for a period of about 3 secs. In this period the squelch switch will be turned ON and the AF signal will then reach the loudspeaker.

SIGNAL STRENGTH DETECTOR

The signal strength detector generates a DC voltage to light the LED bar at the display unit (module 7). The circuit consists of a logarithmic amplifier and a buffer amplifier.

Logarithmic Amplifier

The AGC voltage is fed to the input of the operational amplifier U03/4. With the potentiometer R76 the output voltage is adjusted so that the first LED in the bar is just about to light with no antenna connected to the receiver. Because of R69, R72, and D12 the amplifier has an approximately logarithmic characteristic, which means that the RF signal level must be much higher to light the last LED's than to light the first LED's.

Buffer Amplifier

The output from the logarithmic amplifier is fed to a voltage divider, which consists of the resistor R213 and the transistor Q18. With this voltage divider it is possible to ground the signal strength voltage and thereby turn off the light in the LED bar. From the voltage divider, the signal is fed to the unity gain buffer U01/2. This buffer is included to avoid the loading by the resistor R213, which is necessary for the wanted function of the voltage divider.

h upper side tracks.

5.1. COMPONENT LOCATION RECEIVER UNIT (MODULE 1)

View from component side with upper side tracks.

View from component side with lower side tracks.

TEST CONDITIONS

Receiver frequency : $f_{RX} = 2058.24\text{kHz}$

Receiver mode : J3E/USB

Generator frequency : $f_G = 2059.24\text{kHz}$

Generator level : $V_G = 117\text{dB}/\mu\text{V} \Rightarrow P_G = 4\text{dBm}$

Generator mode : CW

The generator signal must be feed to the aerial socket at the Front End Unit.

● Diode probe measurements
 ▲ Frequency counter measurements
 □ AC-voltmeter measurements

5.2. RECEIVER FRONT END (MODULE 2)

This module consists of a transmit/receive relay and the receiver front end. The front end consists of a receiver input protection circuit, a radio frequency filter unit, a radio frequency to first intermediate frequency (70 MHz) mixer, and a first IF (70 MHz) filter unit.

AERIAL/EXCITER SWITCH

The aerial signal enters the receiver through the aerial/exciter socket J01, when relay RE02 is in RX position. The exciter signal from the power module (8) is connected to relay RE02 through the EX socket J04. When relay RE02 is in TX position the exciter signal will pass through the aerial/exciter socket J01 and a coax cable to the HF power amplifier in T2130. Switching between RX and TX with RE02 is controlled from the microprocessor through register U01 and Q02.

INPUT PROTECTION

Protection of the pre-filters and the first mixer is done with R02, R03, TR01 and the circuit around D05, and it guarantees that the voltages to the pre-filters cannot be higher than about 4.5V. In addition the RX input is grounded with relay RE01 when the transceiver is switched off.

PRE-FILTERS

The pre-filters consists of the following units:

- 100 kHz HPF consisting of L01-L02 and C08
- 385 kHz LPF (1) consisting of L29, C49-C50 and D16-D17
- 385 kHz - 1.6 MHz BPF (2) consisting of L24-L26, C42-C44 and D14-D15
- 1.6 MHz - 4.5 MHz BPF (3) consisting of L20-L22, C36-C38 and D12-D13
- 4.5 MHz - 9 MHz BPF (4) consisting of L16-L18, C30-C32 and D10-D11
- 9 MHz - 18 MHz BPF (5) consisting of L12-L14, C24-C26 and D08-D09
- 18 MHz - 30 MHz BPF (6) consisting of L09-L11, C18-C20 and D06-D07
- 30 MHz LPF consisting of L31-L33, and C54-C56

The switching between the filters is controlled from the microprocessor through U01, U02 and U03.

FIRST MIXER AND IF-FILTER

The first mixer is an active J-FET mixer with good, large signal properties and low noise factor.

The signal is led through the balanced transformer TR03 to the sources of the dual J-FET Q04. The first LO signal from the frequency synthesizer (module 3) is led through the LO buffer (Q03) to give about +17 dBm signal to the gates of the two J-FET transistors. The mixed signals are fed through the balanced output transformer TR04 to the two high order biliteric crystal filters FL01 and FL02 where the wanted 70 MHz signal is selected. The selected signal is then fed on to the receiver PCB (module 1)

5.2. COMPONENT LOCATION RECEIVER FRONT END (MODULE 2).

View from component side with upper side tracks.

View from component side with lower side tracks.

TEST CONDITIONS

Receiver frequency : $f_{RX} = 2058.24\text{kHz}$

Receiver mode : J3E/USB

Generator frequency: $f_G = 2059.24\text{kHz}$

Generator level : $V_G = 117\text{dB}/\mu\text{V} \Rightarrow P_G = 4\text{dBm}$

Generator mode : CW

The generator signal must be feed to the aerial socket at the Front End Unit.

5.3. SYNTHESIZER UNIT (MODULE 3)

The synthesizer unit consists of two phase locked loops. Phase locked loop 1 generates the signal used as injection to the first mixer in the front end module and as the injection to the second mixer in the exciter unit. The PLL1 signal has a frequency range from 70 MHz to 100 MHz in steps of 10 Hz.

Phase locked loop 2 generates the injection signal to the first mixer in the exciter unit and the injection signal to the second mixer in the receiver unit. The PLL2 signal changes between two frequencies 80.7 MHz and 59.3 MHz when the transmitted or received sideband is changed between upper and lower sideband.

PHASE LOCKED LOOP 1

PLL1 operates as a fractional synthesizer. This means that the dividing figure in the loop can be set to a non-integer number, making it possible to get a frequency resolution at the VCO output which is smaller than the reference frequency in the loop. The reference frequency is 40.96 kHz and the frequency resolution is 10 Hz. The reference frequency is derived from a TCXO, which oscillates at 10.73152 MHz. Furthermore the TCXO signal is used as carrier signal for both detector in the receiver and SSB generator in the exciter.

The principle in a fractional synthesizer is that the integer number dividing figure N_i in the loop is changed at particular times to (N_i+1) determined by the value of fraction number F . By this method the mean frequency of the VCO is increased as illustrated in the example below:

In the example the integer dividing figure is changed every fourth reference cycle implying an increase in mean VCO frequency.

Because of the change in the integer number, dividing figure spurious sidebands occur at the VCO output. These sidebands have to be reduced and this is done through a correction signal fed to the phase detector. The correction signal is generated in the API (Analog Phase Interpolator) circuit.

VOLTAGE CONTROLLED OSCILLATORS

The frequency range from 70-100 MHz is covered with four independent oscillators:

VCO I	:	70	-	77.5	MHz
VCO II	:	77.5	-	85	MHz
VCO III	:	85	-	92.5	MHz
VCO IV	:	92.5	-	100	MHz

5.3. SYNTHESIZER UNIT (MODULE 3) cont.:

The oscillators are in principle identical and each of them is built-up around an earthed drain FET amplifier, where the output signal is fed back to the input by means of two capacitors. The ratio of the capacitors determines the amount of feed-back in the oscillator. The oscillator frequency is determined by the LC circuit located on the gate of the FET, and the tuning of oscillator frequency is done by means of variable capacitance diodes.

The output signal from the VCO's is led through switch diodes D2, D5, D7, and D10 to a common buffer amplifier Q13, which buffers the VCO signal for prescaler buffer and L0 buffer respectively.

Selection of the wanted VCO circuit is done by Q1, Q3, Q4, Q6, Q7, Q9, Q10, and Q12. The control of these transistors is done by serial to parallel register U1.

PASSIVE LOOP FILTER

The components R28, R31, C11, C51, C54, and L22 constitute a chebychev lowpass filter with cut-off frequency equal to approximately 10 kHz.

The major task of the passive filter is to prevent spurious signals arising from the phase detector and divider circuit, to modulate the VCO and generate sidebands to the VCO output signal.

ACTIVE LOOP FILTER

The filter consists of U16, C66, R33, and R38. The filter secures stabilization in the loop system and is of vital importance in determination of the loop system bandwidth.

PHASE DETECTOR

The phase detector is of the sample and hold type. The detector consists of a sequential phase detector followed by the current switch, the ramp generator and the sample and hold circuit.

U26 together with U27 form the sequential phase detector which converts the phase difference between the reference signal and the signal from the programmable divider to a square wave signal measurable on U26 pin 6. The duty cycle of the square wave signal is inverse proportional to the phase difference.

The sequential phase detector controls the current switch, which is built-up around Q25, D17, R93, D16, and D15. When the signal on basis of Q25 is at high state, D16 is switched on, the potential on the cathode of D15 is increased, and D15 is switched off.

When the signal on basis of Q25 is at low state, D16 is switched off, the potential on the cathode of D15 is decreased, and D15 is switched on. The amount of current flowing through D15 and D16 respectively is determined by the current mirror circuit described elsewhere.

The ramp generator, built-up around U21 and C112, integrates the current drawn from U21 pin 2 in regard to time. The ramp generator output voltage is then linear in regard to the size of current flowing through the switch diode D15 and the period of time the diode is switched on.

Q24 connected in parallel to C112 constitutes a switch, which resets the ramp generator by discharging C112.

The switch is open when the gate voltage is at low state and vice versa.

The ramp generator and current switch connected with the sequential phase detector imply a phase detector where the output voltage, in a certain period of time in every reference cycle, is linear in regard to the phase

5.3. SYNTHESIZER UNIT (MODULE 3) cont.:

difference between the reference signal and the signal from the programmable divider. In this period the output voltage has to be sampled and held and this is done by the sample & hold circuit, consisting of U19, R64, C95, Q19, and R77.

Q19 functions as the switch, which carries out the sampling. The switch is open when the gate voltage is at low state and vice versa.

C95 is charged to the phase detector voltage through R77 when the sample switch is closed, and carries out the hold function when the sample switch is open.

The voltage on C95 is led to the active loop filter through the voltage follower U19.

CURRENT MIRROR

The current mirror is built-up around transistor array U20 and the circuit generates reference current for the phase detector and the API-circuit.

The current mirror is so designed that the ratio between reference current for phase detector and API-circuit respectively will be kept as a constant regardless of the temperature. A change in one of the currents will be reflected or mirrored into the other.

The nominal value of reference current for the API circuit can be adjusted by means of potentiometer R88.

CONTROL SIGNAL LOGIC

The circuit is built-up around one 8-bit counter U32, which is clocked by the input signal to the reference divider. The clock frequency is 5.36576 MHz.

The counter is reset by the output signal from the reference divider.

The control logic delivers reset signal to the ramp generator and sample signal for the sample & hold circuit. The output signals from the circuit are generated through detection of which state the 8-bit counter is in, and the detection is done by means of the logical circuitry formed by U25 and U29.

API CIRCUIT

The circuit delivers signal to the modulus control logic and correction signal (API voltage) for the phase detector. The circuit is built-up around a 12-bit digital accumulator constituted by U2, U3, U4, U7, U8, U9, and U12 containing a fraction register, a binary adder, and a sum latch.

Overflow information from the binary adder is led to the modulus control logic and implies a change in the integer number dividing figure in one reference cycle.

In every reference cycle the contents of the accumulator is renewed by clocking the sum latch, the clocking is controlled by the control logic circuit.

The output from the binary adder is led to a 12-bit D/A converter U14, which in connection with OP. AMP U18 generates the API voltage.

The reference current to the D/A converter is derived from the reference current to the phase detector by means of the current mirror and is led through the current switch and current buffer & filter to the D/A converter. D11, D12, Q16, and Q15 constitute the current switch, which adjusts the mean value of the reference current to the D/A converter as a function of the integer number dividing figure in the loop.

5.3. SYNTHESIZER UNIT (MODULE 3) cont.:

When the signal on basis of Q15 is at high state, D11 is switched on and D12 off and vice versa, and by changing the duty cycle of a square wave signal on basis of Q15 the mean value of the current to the D/A converter can be adjusted.

Control of the current switch is carried out by the 1/N correction logic, which as a function of the output from the programmable divider and the output from the prescaler produces a square wave signal measurable on U13 pin 13 where the duty cycle is varied as function of the integer number loop dividing figure so that the duty cycle increases for decreasing VCO frequency and vice versa.

From the current switch the current is led to buffer & filter constituted by Q14, C84, and C85, which buffers and filters out the reference current to the D/A converter.

MODULUS CONTROL LOGIC

The modulus control logic is constituted by U28 and U23, which as a function of overflow signal from the accumulator, prescaler output, modulus control signal from the programmable divider and output from the 1/N correction logic, generates modulus control signal for the prescaler.

The circuit does not effect the modulus control signal from the programmable divider when the loop dividing figure includes a fraction part, the prescaler modulus shall be changed in one prescaler output period from 32 to 33, if there is a reference cycle where overflow signal is given from the digital accumulator. This change of prescaler modulus implies the needed change of dividing figure to increase the mean frequency of the VCO with a fraction of the reference frequency, and the change is timed through the modulus control logic.

DIVIDER CIRCUITS

The programmable divider consists of a dual modulus prescaler U22 dividing by 32/33 and a programmable divider included in U24. The integer number dividing figure is latched into U24.

The reference divider consists of a D-FF U31 followed by the programmable reference divider U30.

The division ratio of U31 is 2 and the division ratio of U30 is 131. This implies a total division ratio of 262.

BUFFER CIRCUITS

The VCO signal is led from the VCO buffer into L01 buffer and prescaler buffer.

The L01 buffer consists of Q17 and Q22 and the buffer generates the necessary power level for both receiver and exciter modules.

The output of the buffer is led to relay RE01, which feeds the signal to receiver and exciter respectively, dependent upon whether the transceiver is in transmit or receive mode.

The control of RE01 is carried out by serial to parallel register.

The prescaler buffer consists of Q18 and Q21 and the major task of the circuit is to prevent spurious signals created in the prescaler from being added to the VCO signal and through that imply spectral impurity of the L01 signal.

The TCX0 signal is led to the TCX0 buffer, which consists of Q27 and Q26.

The buffer delivers signal for the reference divider and carrier reinjection signal for both receiver and exciter modules.

5.3. SYNTHESIZER UNIT (MODULE 3) cont.:

PHASE LOCKED LOOP 2

The change between transmitted and received upper and lower sideband is generated by a frequency change in PLL2 as illustrated below.

USB Receiver

f_m = Modulation frequency
 $f_{IF2} = f_{L01} - f_{L02} - f_{RF} - f_m$

The modulation frequency f_m changes sign meaning that a received upper sideband signal will pass through the 10.7 MHz lower sideband IF-filter.

LSB Receiver

f_m = Modulation frequency
 $f_{IF2} = f_{L02} - f_{L01} + (f_{RF} - f_m)$

The modulation frequency f_m does not change sign meaning that a received lower sideband signal will pass through the 10.7 MHz lower sideband IF filter.

RE2100 / R2122
4-0-25743

The diagram illustrates the PLL control system for the MC145158. It starts with a TCXO (Temperature Compensated Crystal Oscillator) connected to a divider chain consisting of a ÷2 stage followed by a ÷131 stage. The output of the ÷131 stage is fed into a phase detector (PH). The PH also receives a feedback signal from the output of the modulus control block (N, A). The output of the PH is filtered by two stages, $F(s_1)$ and $F(s_2)$, and then fed into two voltage-controlled oscillators, VCO1 and VCO2. VCO1 is connected to the ÷2 stage of the divider chain. VCO2 is connected to a 2-modulus prescaler (P, P+1) and a comparator (>). The output of the prescaler is fed into a comparator (<). The output of the comparator (<) is fed into the modulus control block (N, A). The output of the modulus control block (N, A) is fed into the PH. The output of the comparator (<) is also fed into a frequency error signal block (fvco), which is then used to control the VCO2 frequency. The final outputs are L02 to RX and L01 to TX.

$$f_{VCO} = f_{TCXO} \frac{1}{R} (N \cdot P + A) \quad P \text{ chosen to } 32.$$

$$f_{TCX0} = 10.73152 \text{ MHz}$$

When lower sideband is chosen the following counts are read into the divider U35. R = 2 x 131, N = 61, A = 19, this gives $N \cdot P + A = 1971$ and the lock frequency is $f_{VCO} = 80,732.160$ MHz.

The circuit contains two similar VCO's. One is active in LSB mode and the other is active in USB mode.

D20 and R120 which are connected to the gate of the oscillator transistor prevent the gate source voltage from becoming positive which will cause the oscillator noise to increase.

The oscillator which is active in the USB mode is built around the transistor Q33. Coil L37 parallel with C150 and C149 in combination with the variable capacitor D22 form the main part of the frequency determining elements.

5.3. SYNTHESIZER UNIT (MODULE 3) cont.:

D23 and R133 which are connected to the gate of the oscillator transistor prevent the gate source voltage from becoming positive which will cause the oscillator noise to increase.

To activate the oscillator U01. Pin Qg is "high" which means that the transistors Q32 and Q35 are on supplying the oscillator transistor with DC voltage.

When one oscillator is supplied with DC voltage the other is off.

The DC supply to the oscillator switches the diode D21 or D24 on and thereby supplies DC voltage to the oscillator buffer transistor Q36. From this transistor the local oscillator signal is fed to the prescaler buffer and to the output local oscillator buffer.

PRESCALER BUFFER

From the oscillator buffer transistor Q36 the signal is fed through the network consisting of R159 and C180 to the grounded basis transistor Q38. The local oscillator signal is amplified here and fed through the attenuator R168/R170 and the amplifier transistor Q40. The result is an amplitude stabilized signal which is fed to the prescaler U36.

PRESCALER AND DIVIDER

The programmable divider consists of a dual modulus divider U36, dividing by 32/33 and a programmable divider included in U35.

The division ratio is determined by the number latched into U35 and together with U36 the divider works as a conventional dual modulus divider with the modulus control from U35 controlling the prescaler U36.

The reference frequency divider is included in U35.

The reference frequency input on pin 1 has the frequency 5,365.760 MHz and the reference division ratio R read into U35 is 131 leading to a reference frequency of 40.96 kHz which can be monitored on pin 13. This 40.96 kHz signal is used as the reference signal to the phase detector. The variable frequency to the phase detector is the VCO frequency divided with the read in "division ratio". This ratio is 1447 when USB mode is chosen, and by LSB mode 1971 leading to the two phase lock frequencies in USB of 59,269.120 MHz and in LSB mode 80,732.160 MHz.

PHASE DETECTOR AND LOOP FILTER

The phase detector is an integrated part of U35. The input reference frequency f_R is 40.96 kHz which can be monitored on pin 13 and the input variable frequency f_V can be monitored on pin 3. The three-state output of the phase detector produces a loop error signal which is used with the loop filter to control the VCO. The phase detector output is for frequency $f_V > f_R$ or f_V leading, negative pulses. For frequency $f_V < f_R$ or f_V lagging, positive pulses and for $f_V = f_R$ and phase coincidence, the output is in high impedance state.

The loop filter consists of two parts. The first part of the loop filter built around the amplifier U34 and the R/C network R118 and C131 take care of the loop characteristic. The second part of the filter consisting of L34, L35 and C141/C143/C146 is a passive lowpass filter which removes the remaining part of the 40.96 kHz reference signal from the VCO control signal.

5.3. SYNTHESIZER UNIT (MODULE 3) cont.:

OUTPUT LOCAL OSCILLATOR BUFFER

From the oscillator buffer transistor Q36 the VCO signal is amplified in transistor Q34 and filtered in the lowpass filter consisting of C176, L40, and C177. Before the signal is fed to the output terminal it is amplified in transistor Q37 and fed through the relay RE2.

When the relay is activated the VCO signal is fed into the first mixer on the transmitter module. The diode D26 is conducting and thereby grounding the remaining part of the signal to the receiver module. When the relay RE2 is not activated the diode D26 is reversed and the VCO signal is fed to second mixer on the receiver module.

SYNTHESIZER WAVEFORMS

5.4. EXCITER UNIT (MODULE 4)

The exciter module is modulating an audio frequency into a carrier frequency. After some amplification and filtration the modulated signal is led to the power unit (module 8) for further amplification and filtration.

AF SELECTOR

The exciter unit is able to handle three kinds of AF signals: the microphone signal, the tune/alarm tones, and some telex signals. The wanted signal is selected by the analog switch U01, which is switched on by means of the OP-amp. U03. To select the microphone input, the microprocessor sends an 8-bit signal to the shift register U07, which controls the analog switch U01/2 by means of U03/4. The other two AF inputs can be selected in the same way.

From U01 the AF signal is led to the amplifier U02 and through C10 to the compressor circuit. To handle the AF signal the analog switch U01 and the OP-amp. U02 are biased with R04.

COMPRESSOR AND AF LIMITER

The audio signal from the amplifier U02 is attenuated by means of R20 and the FET Q01. A DC voltage applied to the gate of Q01 controls the attenuation.

From the amplifier U04/1 the audio signal is split into two ways. One way to the AF limiter and another way to a dual rectifier. The rectified audio pulses are compared to a DC level determined by means of D02 and R35. A strong audio signal creates new pulses out of the comparator amplifier U04/2 and into C25, which gives a DC voltage to the gate circuit of Q01.

If the audio signal is so quick and strong that the compressor is unable to handle it, the transistors Q02, Q03, and Q04 cut the peaks of the signal. The cutting symmetry is adjusted with R57.

CARRIER LIMITER AMPLIFIER

To ensure a constant carrier level to the modulator U05, the transistor Q05 works as an amplitude limiter. The carrier input signal from the synthesizer unit is amplified in Q06. The transistor Q07 controls the bias voltage of Q05 and Q06. To switch on the carrier signal to the modulator, the transistor Q07 is switched on by means of U07 or by an external wire connected to pin 19 on plug P01.

MODULATOR

The carrier signal from the carrier limiter amplifier Q05 is applied to the modulator U06 pin 10. The audio signal from the AF limiter Q04 is applied to U06 pin 1. The audio signal is multiplied by the carrier signal in U06, and the resulting modulated signals on pin 12 and pin 6 are added in the transformer TR01. The output from TR01 is a double sideband signal with suppressed carrier. With R190 the carrier suppression can be adjusted.

5.4. EXCITER UNIT (MODULE 4) cont.:

MODULATION LEVEL AMPLIFIER

The modulated signal is led to the voltage divider R77, R78, and R85. The mode selector circuit is forward biasing one of the diodes D10, D11, or D12 to select the wanted modulation level for the modulation mode in question. The wanted modulation level is led to the amplifier Q09, and then to the SSB crystal filter where the unwanted upper sideband is removed. The amplification is adjusted with R87.

CARRIER LEVEL AMPLIFIER

The carrier signal is led to the voltage divider R95 and R96. The wanted amount of carrier insertion for R3E or H3E mode is selected by one of the diodes D14 or D15 and led to the amplifier Q10. The diodes D14 and D15 are controlled by the mode selector circuit. In the J3E mode no carrier is wanted, and therefore D14 and D15 are reverse biased, while D18 is forward biased to short-circuit any carrier signal for Q10.

MODE SELECTOR

Only two bits from the shift register U07 (pin 15 and pin 1) are used to control the mode selector U08 to select the right combinations of carrier level and modulation level for the mode in question. The outputs from U08 are forward biasing or reverse biasing the switch diodes in the carrier level amplifier and in the modulation level amplifier.

CARRIER INSERTION AND RF LIMITER

The SSB signal from the crystal filter FL01 is led to transistor Q11. The wanted amount of carrier signal from transistor Q10 is added to the modulated SSB signal on the collector of Q11. The output from the transformer TR02 is connected to a peak to peak RF limiter network, consisting of the diodes D19 and D20 biased by the zener diode D21. The signal from TR02 is led to the buffer amplifier Q19 at the input to the step attenuator.

STEP ATTENUATOR AND 1st MIXER

The step attenuator is divided in two parts. Part one consisting of the transistors Q20, Q21, Q22 and Q23 is divided in steps 0.3 dB, and part two, consisting of the transistors Q14, Q15, and Q16 is divided in steps of 4.5 dB.

Part one of the step attenuator is working as a voltage divider, where the SSB signal on the emitter of Q19 is divided by R148 and the parallel connection of the resistors R151, R153, R173, and R175, depending on which one is grounded.

The grounding of the resistors in this attenuator takes place in normal binary code, meaning (0000) is equal to non attenuation and (1111) is equal to full attenuation.

In part two of the attenuator the voltage gain of transistor Q12 will be changed according to the wanted attenuation step. From attenuator step 16, R130 will be grounded, and from attenuator step 48, R113, R140, and R145 will be grounded. The wanted attenuator step is controlled by U09, which converts the received input serial code to an output parallel code which controls the grounding of the transistors in the attenuator.

5.4. EXCITER UNIT (MODULE 4) cont.:

The gain in the amplifier Q12 is adjusted with R120. The potentiometer R159 on the basis of the buffer transistor Q18 is used to adjust the attenuation at step 16 to be 0.3 dB higher than the attenuation at step 15.

The output from Q12 is in U10 mixed with the 1st local oscillator to give an intermediate frequency of 70 MHz. If the local oscillator frequency is 80.7315 MHz, the upper sideband USB is selected. If the local oscillator frequency is 59.2685 MHz, the lower sideband LSB is selected.

70 MHZ IF, 2nd MIXER AND LO BUFFER

The output from the mixer U10 is led to the tuned amplifier Q13. The 70 MHz IF filter is consisting of two monolithic crystal filters FL02 and FL03. From the filter the signal is led to the amplifier Q17 and to the 2nd mixer U11.

Because the 2nd mixer U11 is a high level mixer, it is necessary to amplify the 2nd local oscillator signal. This is done in the LO buffer amplifier Q24.

RE2100 4-6-25634C

5.5. PROCESSOR UNIT (MODULE 5)

The processor module has been built up around a microprocessor of the type HD63B03VP with belonging 8.005 MHz crystal. The purpose of the microprocessor is to control the other modules in the RE2100 by means of a Serial Peripheral Interface Bus (SPI), and to scan the keyboard. Furthermore the processor must also control the Serial Communication Interface Bus (SCI), also called the SP-BUS.

MICROPROCESSOR

The microprocessor module is normally equipped with a ROM less processor, type HD63B03VP, however mass produced types may also occur. The placing of a strap in P02 informs the processor from where to read the programme. If the strap is placed between pin 1 and pin 2, the programme is read from the internal ROM store. If the strap is placed between pin 2 and pin 3, the programme is read from the external store (27C128/27C256). The internal clock frequency of the processor is 2 MHz.

WATCH DOG

The microprocessor supervising circuit U15 works as watch dog and power sense.

In U15, pin 6 (watch dog input) the level must change at least once every 1.6 sec. If not, the U15 generates a reset pulse to the microprocessor.

Power fail input U15, pin 4 detects when the 9V supply falls below 7.0V. In this case, the microprocessor receives an interruption via power fail output U15, pin 5. The programme starts storing data in the EEPROM. This function is used when the receiver is switched off (see the paragraph below: ON BOARD POWER SUPPLY).

When VCC to U15 is below 4.65V the reset output U15, pin 7 goes low, and the U15 does not generate a reset to the microprocessor until the VCC is above 4.75V again.

MEMORY

The microprocessor has two memory circuits. One for programmes and one for data.

The programme memory U06 is a 16 or 32 kbyte PROM, e.g. the type 27C128/27C256 with a max. access time of 250 nS. If 16 kbyte is used, the strap in P01 is mounted between pin 2 and pin 3. When 32 kbyte is used, the strap is mounted between pin 1 and pin 2.

The data memory U05 is an 8 kbyte EEPROM, e.g. the type 28C64 with max. access time of 250 nS. Furthermore it must contain page mode programming of min. 16 kbyte. U15 contains data, such as frequency tables, country versions, scanning tables, and latest set-up after the receiver has been switched off.

KEYBOARD

The keyboard module 6 has been built-up as a 4x8 matrix of which 26 keys are used. The keyboard is scanned by means of 4 ports from the microprocessor and the data bus. When the processor reads from the keyboard, access is made to the bus driver U04.

5.5. PROCESSOR UNIT (MODULE 5) cont.:

EXT. PORT

The Bus Driver U19 acts as an 8-bit input port, which is connected to the internal Data Bus.

ON BOARD POWER SUPPLY

On this PCB, 3 power supplies are found, i.e. 5VA, 5VB and -5VB.

5VA (U16) supplies the microprocessor, memory, watch dog, baud rate generator, and address select.

5VB (U17) supplies the remaining circuits, using +5V.

-5VB (U18) supplies half of the SP-Bus transmitter.

Power supply 5VA is a low drop 5V regulator. The power supply also works as a power back-up, when the 9V supply disappears. C11 is able to keep the supply for the microprocessor for approx. 50 mS after the 9V supply has disappeared.

The microprocessor spends approx. 20 mS for storing the data in U05. A parallel connection of C14 and C45 has been carried out in order to keep the serial resistance below 1 ohm at low temperatures.

Power supply 5VB is a standard 5V regulator (LM340T5).

TUNE/ALARM TONE GENERATOR

Tune and alarm tones are generated in the microprocessor and sent out in P26.

Tune tones consist of two simultaneous frequencies of 1000 Hz and 2000 Hz. The microprocessor generates a signal of 2000 Hz. A divider (1/2 U02), enabled by P54, divides the signal to 1000 Hz, and the transistor Q01 adds the two signals before they are passed on to the exciter unit (module 4).

The alarm tones consist of two changing frequencies of 1300 Hz and 2200 Hz. Both tones are generated in the microprocessor. The divider (1/2 U02) will be disabled.

DISTRESS DRIVER

When a distress frequency (2182 kHz) is selected, the microprocessor port P20 goes high and Q03 will be able to source up to 14 mA. The distress signal is used when connection is made to SAILOR scrambler CRY2001 or CRY2002.

SERIAL PERIPHERAL INTERFACE BUS (SPI)

The SPI-Bus is a synchronous serial bus supplying the other units with data. The clock speed is 38.5 kHz. Through 4 drivers in U10, the clock and data are passed on to the modules which are connected to the SPI-bus. The strobes for the various modules are generated in SPI address select U09. Through the 4 ports of the microprocessor, P60 - P63, an address is set up, which is suitable for the module which is going to receive the serial data.

BAUD RATE GENERATOR

The baud rate generator U01 and 1/2 U02 divide the internal clock frequency of 2 MHz by 26 by means of a duty cycle of 50 per cent. The divided frequency is equal to the frequency which must be added to the internal serial communication interface (SCI) of the microprocessor, so that the baud rate of the SP-Bus will be 4800 baud.

5.5. PROCESSOR UNIT (MODULE 5) cont.:

SP-BUS TRANSMITTER AND RECEIVER

The communication from and to the RE2100 is time multiplexed data bus. It is implemented with a 50 ohm coaxial cable, terminated in both ends, and a transmitter and a receiver in each connected unit.

The RE2100 is the master and a number of slaves may be connected to the SP-Bus. When a slave (except from T2130) wants to be called, the slave sends an interrupt to RE2100 on the SP-Bus INTERRUPT. The transmitter and the receiver are identical in each unit connected to the SP-Bus. The transmitter output is normally in high impedance state except when transmitting on the SP-Bus. The transmitter consists of two gates, U13/1 and U13/2 (74HC00), a transistor Q04 (BC558) for level shifting, and two complementary output transistors Q05 (BC640) and Q06 (BC639). The transmitter is connected to the microprocessor P24 (Transmit Data), and P55 (Transmitter Enable).

The receiver consists of an op-amp, (U12/1, MC1458) which is configured as a Schmitt Trigger and two diodes D04 and D11 for level conditioning. The receiver is connected to the microprocessor P23 (Receive Data). As the levels on the SP-Bus approximately match the RS232C standard, it is possible to connect an RS232C to the SP-Bus. The cable terminations (jumper P04) must be removed when the external RS232C is to transmit on the bus.

5.5. COMPONENT LOCATION PROCESSOR UNIT (MODULE 5)

View from component side with upper side tracks.

View from component side with lower side tracks.

4-0-25635K

5.6. KEYBOARD UNIT (MODULE 6)

The keyboard consists of a 4x8 matrix of which 26 keys are used. One side is connected to the microprocessor data bus by an 8 bit driver. The other side is connected to 4 of the microprocessor ports. By setting the 4 ports high and reading the data bus alternately it is possible to determine which key has been activated. In this way the keyboard is scanned 100 times per second. The keyboard light, consisting of 13 LEDs divided in 5 columns, is controlled by an open collector (Q02) on the display print PCB, module 7. The power in each column is approx. 8.5 mA.

Keyboard Unit (6)

5.7. DISPLAY UNIT (MODULE 7)

The display module uses 13 pcs. 7 segments (U08-U20), 12 pcs. LED (D03-D14) and 1 pc. LED-bar (U01) for reading-out information to the operator.

DISPLAY DRIVER

The display driver U03-U05 is a serial read-in driver, which is able to drive 34 segments. U03, U04, and U05 in combination drive the RX and TX display and the individual LEDs, except from D06 and D07 (indication of Dummy Load and Tune)

The 34 bit data for each display driver is read-in serially by means of the internal SPI-Bus. The power in the individual segments is determined by the power in Brightness input, pin 19. The Brightness control circuit consists of Q03, Q04, Q05, and U07. The adjustment takes place in 4 steps:

- 1) OFF. All segments are off. U06, pin 15, 1 and 2 are high,
- 2) Min. The power in the segments is approx. 0.5 mA. U06, pin 15 goes low.
- 3) Normal. The power in the segments is approx. 1.0 mA. U06, pin 2 goes low.
- 4) Max. The power in the segments is approx. 3.5 mA. U06, pin 15 goes low.

DUMMY LOAD AND TUNE LED

For read-out of the dummy load and tune functions, 2 separate LED's are used. These LEDs cannot be reduced or switched off after the functions have been selected. The two LEDs are controlled by U06 (74HC595) an 8 bit serial register, which is also supplied by the internal serial SPI-Bus.

KEYBOARD LIGHT DRIVER

When the light in the keyboard is turned on, U06, pin 3 goes low, after which Q02 is turned on and supplies the 13 pcs. LEDs on the keyboard with 8V. The zener diode D15 (5V1) prevents Q02 from turning on when U06, pin 3 is high.

LED-BAR AND LED-BAR DRIVER

For visual read-out of aerial power and RF-gain, a 10 segment LED bar with driver, i.e. U01 and U02, is used. The two signals are added in D01 and D02, and through the filter R01, R02 and C02 passed on to U02, pin 5. +5V on U02, pin 6 is reference for the signal. The individual segments in the LED bar are turned on by a rise in the signal of 500 mV.

The brightness of the LED bar is controlled by bits 4 and 5 in the 8 bit serial register U06. The adjustment follows the 4 steps, which also apply to brightness in the display. In order to be able to switch off the LED bar completely, Q01 is set off when U06, bits 4 and 5 are high.

5.8. POWER UNIT (MODULE 8)

REGULATORS

The power module receives three voltages +9V, +18V, and -18V from the power supply placed in the transmitter T2130. Seven regulators are converting these voltages to the different working voltages used in the RE2100.

U01 and U02 deliver +15V and -15V only to the exciter module. If the transmitter has not been used for two minutes the microprocessor shuts down the regulators U01 and U02. This takes place via the shift register U07-4 in the exciter module and the transistors Q01 and Q02. This is done to save power consumption in the stand-by position. Regulator U06 is factory adjusted to deliver 5.25V output voltage.

RF AMPLIFIER AND FILTER

The transistors Q03, Q04, and Q05 form an RF amplifier to boost the exciter output to a level required by the transmitter. The output level can be adjusted by means of R30. To reduce harmonics produced in the exciter module a low pass filter is placed between Q03 and Q04. The RF output is a ready to send signal.

5.8. COMPONENT LOCATION POWER UNIT (MODULE 8)

Seen from component side with upper side tracks.

Seen from component side with lower side tracks.
